Occupational Medicine and Hygiene

Its Rôle in Britain in Wartime*

E. R. A. MEREWETHER, M.D., M.R.C.P., F.R.S.Ed., F.A.P.H.A.

*Barrister-at-law, one of H. M. Medical Inspectors of Factories in Great Britain,
Lecturer on Industrial Hygiene, Aberdeen University, Aberdeen, Scotland*

BEFORE I tell you of our experiences since the war broke out, of our problems and our efforts, I should I think speak of the pre-war structure on which we have had to build.

The home of the factory worker and the place where he works are entirely different worlds; the purpose of the one is to serve his individual family, that of the other to serve the needs of industrial processes. This variance of function and environment imports a host of special risks to health and safety, which differ in each occupation and in each factory and are different from those encountered when not at work. Communities, therefore, have had to devise special methods of coping with these occupational problems. In Great Britain, the duty of initiating and enforcing minimum standards of health and safety in factories and mines and in some other occupations is the responsibility of the Central Government. The duty of installing and

maintaining these minimum standards is obviously for those who work therein, that is to say, both employer and the worker.

Progress in the prevention of occupational hazards in Great Britain, therefore, is the result of team work. The broad pattern we see is the Central Government, employers, and workers, with their various associations and teams of experts, all working by different routes toward a common goal. Over all, the community as a whole holds a watching brief, which keeps everybody on his toes. This self-responsibility of each section is keenly felt and definitely appreciated, and is the result of the enforcement by law of minimum standards throughout the country.

This does not mean that the conditions in every factory, for example, are alike and that the best is the same as the worst; far from it, a proportion of the factories are constantly being jolted into a proper appreciation of their obligations, but many, and I think I may say the majority of factories, aim at a higher standard and attain it. This un-

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1941.

doubtedly produces a competition of good will, and ultimately the legal minimum standards are raised by general agreement.

One has only to compare the minimum standards of the Factory and Workshop Act, 1901, with those of the Factories Act, 1937, to appreciate the outstanding advances made in the intervening years in this way. This latter Act also, after very full debate in Parliament, gave to the Minister from time to time great powers to raise standards and accelerate progress when fact and reason require it. Without the basis of law there can be no order and without order, no progress.

The permanent Departments of the Central Government dealing with health, safety, and welfare in factories and in mines and quarries respectively, are the Factory Department of the Ministry of Labour and National Service and the Ministry of Fuel and Power. The executive powers are exercised by H.M. Chief Inspector of Factories and H.M. Chief Inspector of Mines respectively. They are assisted by deputy chief inspectors, superintending inspectors (for divisions), and district inspectors with junior inspectors (for the ultimate subdivisions of the country), together with a number of specialist inspectors with special medical, electrical, engineering, physical, and chemical, etc., qualifications.

The term "H.M. Inspector of Factories" is over a hundred years old and much valued by the Inspectorate: yet sometimes it misleads visitors by suggesting that our job is analogous to that of a policeman. Of course, we have to maintain legal standards, but that is only one of many duties. Nowadays to inspect is to look and to inquire and, having looked and enquired, to *aid*—and this applies to both sides, employers and workers alike.

The Minister of Labour and National Service, Mr. Ernest Bevin, clearly described, last July in Parliament, the

position of the Factory Department in the social services of the country. He referred to its duty of carrying on a great educational work for the safety of the people in industry and its great contribution to the health of our industrial population. He went on, "I think no Department of State has a better record of work for well over a century than this Department can claim. . . . The Factory Department developed a tradition which was twofold and which, I think, in the general administration of industrial legislation, has set a standard in dealing with these problems the like of which does not exist in any other country. It can be described as persuasion with sanctions in the background. This has resulted in giving flexibility for innovations and opportunities for change that one cannot always embody either in regulations or in law."

To you I can perhaps best describe our functions in industry as not so much those of the police, but more like those of a catalyst.

That we must function in some such way is the more obvious when I mention that before the war there were over 280,000 concerns of one sort or another registered under the Factories Act. This number has much increased since, and yet our Chief Inspector, Sir Wilfrid Garrett, has only a total staff of 372 inspectors, at this moment. We can scarcely be accused of surrender to "bureaucracy" here.

You will ask, I think, "how is it possible to cater for all these factories with an Inspectorate of this size?" There is no doubt at all that more work and better inspection could be done with a larger staff, but the gap in peace time between partial achievement and full effectiveness is not perhaps so great as the figures suggest. In the first place the work is compelling in its fascination, and consequently the average weekly output of work per inspector is undoubtedly high.

Secondly, the century old acquaintanceship of industry and the department has ripened into an understanding friendship, and so all sections of industry consciously and materially aid the department's work.

Thirdly, industry on the whole knows quite well those minimum legal standards I have mentioned—they are posted in every factory—and they take considerable pains to comply with them, for employers know that it will not be long before the Inspector for the District hears of any material departure from them. Moreover, if a works acquires a bad reputation in the district and in the local magistrate's court, it takes a lot of living down. Although the fine imposed by the court may be of no account to the firm, the effects of a conviction for a breach of the Factories Act may be profound; certainly in some parts of the country the stigma of having to appear in court to answer a charge is a definite deterrent to wilful negligence. The press too is an extremely valuable aid. Again both the court and the Minister have sweeping powers for dealing with really urgent and bad conditions.

Lastly, because the department is small in number, inspectors know each other personally and the special knowledge and experience of each of his colleagues, and thus the knowledge and experience of the whole department is readily and quickly available for a single firm. Every month the Chief Inspector sends to each inspector, senior and junior alike, his "Monthly Circular," a confidential document which gives the stop-press news on matters of importance—and as it also contains notices of any promotions or transfers, it does not escape careful examination and indexing!

A defect, which I think should be remedied, is that the department has no abstracting bureau of its own. It is true that a number of journals and societies of standing at home and abroad such as the *Journal of Industrial Hygiene*, The

Bulletin of Hygiene, The *Analyst*, The Association of British Chemical Manufacturers, and the Chemical Society, to mention only a few, issue abstracts either privately or publicly, but abstracting for the needs of a particular service, be it public or private, is, as you will agree I am sure, a skilled and delicate business, best done by the particular concern itself, or matters of serious importance to the service will be overlooked.

I should have explained that the term "factory" in the Factories Act has a very wide application. It includes practically all manufacturing establishments, whether they belong to the Crown, municipalities, public corporations, or to private people: as soon as people are employed in building it, working it or pulling it down, the Factory Inspector has duties—he is both accoucheur and mortician, and some employers have rather unkindly suggested that the inspectors' talents lie in the latter direction! It includes warehouses, docks, quays, many work of engineering construction such as tunnels, reservoirs, bridges, camps, and aerodromes. It includes shipbuilding and repairing of ships, whether the vessel is in dry dock, wet dock, or tied up alongside, and also places where sorting, washing, and breaking down of articles by way of trade or for gain is carried on. Do not for a moment think we do all the work—we do not. The strength of the department lies in its legal authority and in the responsibility placed upon the individual inspectors in charge of the 92 districts, as Sir Wilfrid Garrett would be the first to suggest.

The district inspector, a well qualified and experienced man or woman, is the primary, personal, and sensitive anastomosis between industry and the department constantly carrying material between the two structures. The function of the remaining portion of the departmental organization is to nourish and

sustain this living link. To do so it draws upon its own considerable resources, on other government departments, on employers associations, and on trades unions. In turn these draw upon individuals, upon professional, technical, scientific, and legal experts, and in this way the needs of the situation are met. Among these external aids is the Department of the Government Chemist, ready and willing to undertake essential, urgent, and delicate determinations on which often so much depends. Then there is the Medical Research Council with its numerous sections. Two of these sections, the Industrial Health Research Board and the Industrial Pulmonary Diseases Committee are concerned solely with problems of health and hygiene in relation to occupation, and others like the Tuberculosis Committee, deal with subjects on which occupation has an intimate bearing.

The Department of Scientific and Industrial Research, which includes the National Physical Laboratory and the Food Investigation Department, are important sources of information. With the Ministry of Health, whose Chief Medical Officer, Sir Wilson Jameson, had the privilege of addressing you at your Conference last year, we work in the closest possible relationship.

The Local Authorities, corresponding roughly with those of your towns and cities—with their Medical Officers of Health, who have some duties of a general character, not relating specifically to occupation in factories—also give valuable help.

Close contact with the Trades Union Congress and its constituent trades unions, and equally with the many employers associations of particular industries, such as the Engineering and Allied Employers Federation and the Association of British Chemical Manufacturers, is essential for the complete functioning of the department. There are also other important independent bodies, such as

the Royal Society for the Prevention of Accidents, The Industrial Welfare Society, The Royal College of Nursing, and the Association of Industrial Medical Officers, some or all of whose activities are related to the subject we are discussing.

A unique aid to progress is provided by the activities of the Joint Industrial Councils for the various industries. These are composed of representatives of employers and workers, and the oldest is the National Council for the Pottery Industry. Among other great achievements, this Council, with the assistance of the department, succeeded in abolishing the main risk of silicosis in the china section of the industry by substituting alumina for powdered flint for bedding the ware.

Last, but not least, are the Examining Surgeons, formerly called Certifying Surgeons. There are 1,700 of these members of the medical profession distributed throughout the country, most of them engaged in the general practice of their profession.

They are appointed to carry out particular duties under the Factories Act and the Workmen's Compensation Act, under the general control of the Factory Department. Their office is of considerable antiquity, nearly as old as that of Inspector of Factories.

You will see now, I hope, how the small factory department works, and why I have suggested that it functions as a catalyst. It observes, accepts, and collects basic facts from industry and elsewhere which have any bearing on health, safety, and welfare, assesses their value and importance, makes inquiries and investigation, and, when its own knowledge and experience do not suffice, submits special points of difficulty to experts competent to deal with them.

Its specialist inspectors are in close touch with all the institutions and persons especially concerned with their particular problems and frequently get

advice from them. Other problems are settled by small committees of experts set up to advise the Chief Inspector; in this way the department keeps in close touch with outside opinion and is able to draw on wider sources of knowledge than could be supplied by any official research institution. The field work of actual research is often carried out by its own inspectors, and through them a solution is often reached; but if the subject proves too big it is handed over to outside bodies to carry through the full examination of the problem. It considers its findings with the twofold object of providing the solution to the problem and determining the most practical and feasible application to industry of any remedial measures required, and then returns the results and the department's recommendations to industry. At the same time it enforces the practical minimum legal standards in these matters. But beyond all, the inspector must be impartial and keep inviolate the many secrets and confidences entrusted to him.

And so, I think you will agree that the Inspector of Factories has a happy, friendly, and fascinating, if exacting job.

EFFECTS OF THE WAR

I think history will stress two factors as having a preponderating influence in shaping our war effort. One is the disparity between Germany's population and our own, and the other is the unpleasant proximity of enemy activity to much of our daily life. The country, therefore, has to insure that every man, woman, and young person contributes his utmost to the common aim, and that his individual effort is so applied and distributed as to minimize the effects of possible enemy action. The Government steadfastly implements this decision, and the resulting upheaval in the life of the individual has to be experienced to be appreciated.

Mr. Ernest Bevin, the Minister of

Labour and National Service, is, of course, charged with the mobilization and use of our man power in the widest sense and never for one moment has the requirement of labor and national service for everyone been forgotten.

As he explained to Parliament, it was obvious that there would be many problems of an industrial character not entirely new, but certainly more comprehensive, that would have to be dealt with as the war proceeded. In consequence, the Factory Department was transferred from the Home Office to the Ministry of Labour and National Service in June, 1940, to facilitate this work since, as the Minister explained,

... the transfer gave to the Ministry of Labour in its development of the other schemes associated with the mobilisation of man power, valuable experience, long tradition, great knowledge of the factories in the Country and contacts which served a double purpose. . . . Therefore, in the first instances, its great value was that it gave us a broader foundation on which to build and at the same time placed valuable experience readily at our disposal.

Thus, many new duties were cast upon the inspectorate. Apart from the inspectors seconded for special purposes such as research, camouflage, lighting, efficiency of blackout, and prevention of explosion, duties in connection with the development of communal feeding in factories, the provision of air-raid shelters, securing the training of factory personnel in first aid, fire fighting and anti-gas measures and the installation of the necessary equipment became part of their daily activities. Schemes for fire watching and fire fighting, welfare arrangements within the factory, measures for the education of new and untrained labor in self-protection, aiding in the concentration of nonessential industries and in the collection and transfer of redundant labor, all caused much additional work. In addition, the vast building schemes for camps, aerodromes, and factories, often far removed from

towns and essential services, became the particular charge of a section of the department.

It was also recognized by Mr. Bevin that the war would introduce another series of problems that would militate against the war effort—the troubles outside the factory, troubles due to traveling in the blackout with restricted transport facilities, troubles of shopping that bear particularly on the housewife doing the double job of running a home and working in a factory, troubles of transfer to new areas and consequent billeting on private families or in hostels, troubles of continuing to keep at work while the home is bombed and the family spends the night in shelters. In fact, it may be said that in the first year of the war these outside troubles put a greater strain on the workers than the strain of additional hours, blackout, etc., inside the factory. To deal with these troubles Mr. Bevin appointed a number of welfare officers located in all the centers of industry, who, because they dealt with the problems outside the factory, have become known as “outside” welfare officers. The work done by these officers has done much to smooth the way toward the war effort that we have now reached.

The inspectorate solved a multitude of day-to-day problems and materially facilitated quick readjustment following on the upheaval, expansion and redistribution of the industrial man power of the country. It will be observed, however, that all these activities are directed to securing the safety, health, and welfare of the industrial population. At the same time, the other bodies already mentioned whose work is complementary to that of the department have also had to expand and adjust their activities to the new conditions. Thus, the Industrial Health Research Board was reconstituted to bring it closer to the needs of the war situation. Dr. J. C. Bridge, the Senior Medical Inspector of Factories,

was appointed to the board, and another of my colleagues, Dr. R. S. F. Schilling, seconded as Secretary, and Professor A. W. H. Ellis has been appointed to the new post of Director of Research in Industrial Medicine.

The board issued several emergency reports and has numerous investigations in hand directed to determining data of essential importance for the more accurate approximation of the human machine to the national effort. The Industrial Pulmonary Diseases Committee, of the Medical Research Council, whose Secretary, Dr. E. L. Middleton, is another of my colleagues, has recently completed its investigation into chronic pulmonary disease in South Wales coal miners, and the council has published Volume 1 of its report. The report correlates x-ray appearances in the lungs with certain characteristic pathological changes not hitherto described. A second volume containing a further series of research reports on the subject is to be published shortly. An extensive program of research on the effects of exposure to TNT was initiated by the Medical Research Council and is being actively carried out. Another report of the Medical Research Council of importance to the subject of our discussion which has just been published, is the *Interim Report of the Committee on Tuberculosis in War-Time*.

The Minister of Fuel and Power also has accelerated progress of new measures for securing the health and welfare of miners, particularly in connection with the employment of juveniles and female workers and in the protection of workers against dangerous dust. Regarding protection against dangerous dust, a new code of Special Rules for Slate Miners has come into force this year, and a Code of Regulations for the Prevention and Suppression of Noxious Dust in Coal Mines is under consideration and is expected to be put into force in the near future. Extension of schemes

for rehabilitation of miners is also fore-shadowed, as also is a considerable increase in the Medical Department of the Ministry.

The Ministry of Supply, a ministry set up wholly for war purposes, is now the largest single employer of labor in the country. It has Royal Ordnance Factories, most of which are new factories which have had to be staffed by labor at first mostly inexperienced. This involved the Medical Department of the Ministry in much planning of preventive measures against occupational diseases, particularly those associated with the manufacturing and handling of explosives, such as toxic jaundice, dermatitis, and other slighter manifestations of exposure to TNT, and disturbances of health due to other types of explosives. Consequently the Ministry has had to set up large medical and nursing services for the supervision of workers employed in the Royal Ordnance Factories. In addition the provisions of hostels and welfare arrangements in these factories, often isolated; billeting; special means of transport to and from work, and numerous matters of welfare generally have been dealt with by the Ministry of Labour; the provision of special rest centers where workers can obtain a holiday in pleasant surroundings away from their dangerous work, is being explored.

Now, some observations on the difficulties of the Factory Department and the measures we have taken may be of interest to you.

First of all we have endeavored to maintain in every factory those minimum legal standards of health, welfare, and safety to which I have referred. This has often been a difficult matter because of the immense dilution of the staff by untrained and experienced staffs substituted in order to permit of the expansion of production. Unfortunately the important general factors in these conditions are: the effects of a pioneer for many years of enemy action, and had a nucleus

overwork, overstrain and too long hours of employment, extension of employment of women in substitution for men, changes in the age distribution of workers, and infestation by lice and scabies and the possibility of epidemics. More important special factors are the incidence of dermatitis, of cases of gassing, and of poisoning.

EFFECTS OF BLACKOUT

This seems to be the most important single adverse factor, with the possible exception of transport difficulties. At the outbreak of war there had to be an immediate imposition of a complete blackout—this had two main effects—first, it interfered greatly with the ordinary natural ventilation of factories, gave greater opportunities for the spread of respiratory infections, and the stuffy atmosphere depressed the human machine. Second, the restriction in natural ventilation definitely caused accumulation of fume in some processes with resulting increase in cases of gassing. Many cases of gassing would never have occurred but for the damping back of fume by emergency methods of preventing glare. You can imagine how difficult it was to black out, for example, bessemer plants and coke ovens, and yet not interfere with the egress of the vast volumes of gas and fume evolved in some of these processes. Further consequences of the blackout and restriction in general ventilation were in some processes a great increase in the temperature to which the workers were exposed: this, together with the lack of air movement, obviously may quickly cause a serious situation.

Better methods of blackout were devised which incorporated light traps and yet permitted greatly improved ventilation. Extended use was made of mechanical methods of ventilation and of air movement and, although I do not suggest that conditions are yet perfect, the major part of this work has been

completed and conditions correspondingly improved.

In some factories emergency methods of obtaining blackout resulted in the work having to be carried out continuously in artificial light. While no evidence of any definite injury to health was found to result from this, it is obvious that a permanent blackout of this character has psychological effects of a depressing character. Steps have therefore been taken to restore natural lighting in daytime wherever possible.

The blackout has undoubtedly been a very important factor in increasing accidents both on the roads and also in particular occupations, for example among dock workers.

EFFECTS OF ENEMY ACTION

These include of course direct injury to workers by enemy attack, mental strain and physical discomfort, disturbance of gas, water, electric supply and transport services, loss of sleep, and irregular food supply. Such effects of enemy action do, of course, definitely slow down production, or under certain conditions stop it temporarily. The most long continued bombing was directed against the London area and people got weary of it, not so much because of the danger, but because of the attendant hardships experienced, including lack of sleep and the very much longer daily effort required to carry out normal duties.

My own view at the end of the winter 1940-1941 was that the Germans would have had to continue their nightly raiding of London for very many more months before they could have succeeded in doing more than partly depressing industrial output in this area. The Londoners stood the winter, dislocation of heating, lighting, transport, and food services well, and with the advent of the longer days and warmer weather nothing the enemy could have done in the way of continued bombing

could have nullified this natural relief. The speed with which bombed factories were got going again was a revelation—production being restarted often within a few hours under tarpaulins.

The tube or subway system of London provided good additional shelters which were dry and warm and a good asset in maintaining individual resistance, although in the earlier stages, before sleeping accommodation, medical supervision, feeding arrangements, and means for quick washing and disinfection of bedding were inaugurated, there were opportunities for the spread of infectious disease and of lice and scabies. However, as it was, in the bombed areas throughout the country after that winter, the people felt like veterans, and experience dispelled the fears of the imagination.

INFESTATION BY LICE AND SCABIES

There has undoubtedly been a great spread of scabies and infestation by lice among the population, but energetic measures on the standard lines and a new order of the Minister of Health, gave the additional powers required by local authorities to deal with the matter. Obviously, lice and scabies are continuing problems in the present circumstances, and continuing energetic measures are required to keep them within bounds. Scabies is not a disease which one can afford to neglect, because of its power of depriving affected workers of their sleep.

With lice, however, the possibility of typhus being introduced into the population has always been the concern of the Ministry of Health. So far, Sir Wilson Jameson told me the other day, there has not been a single case of typhus in the country.

HOURS OF EMPLOYMENT AND OVERSTRESS

Overstrain is an important
of war and part

country has not geared itself up for war in times of peace. A warship has its maximum speed and also its "economical" speed and it is the economical speed which gives its maximum radius of action. So it is with the human machine; its economical speed gives the highest total output over a considerable period of time, but if the human machine is overstrained, the accident rate goes up greatly and faulty workmanship increases also. The elementary principles so well proved in the past tended to be lost sight of and had to be re-emphasized. On the whole, however, it was the vicissitudes of war which necessitated at certain times during the past three years an increase of speed beyond the economical in order to make good the losses. The nation certainly geared itself up after Dunkirk to an unprecedented output which served the pressing necessities, but the inevitable reaction followed, and it is clear again now that the optimum is a $5\frac{1}{2}$ day week with 1 day off and 1 short day. There is then a reserve, which if the necessity arises will permit of temporary spurts to meet vital needs—and there are still vital needs.

The Factories Act lays down limits of hours for all protected persons, that is to say, women and young persons of both sexes between the ages of 14–16 and 16–18 and these have been slightly extended by emergency powers.

The extension to which my country has gone in this respect may be of interest. Briefly, it is as follows: Young persons between 14 and 16 have had their hours extended from 44 to 48 per week, women and young persons from 16–18 of both sexes can have their ~~hours~~ increased by order of the Minister, substitute bottle necked occupations duties upon a week have been worked; special measures the hours of these proportionately the decrease about 54 to 56. a pioneer for many male young persons and had a nucleus allowed to work at

night, but no girl under 18 and no boy under 16 is employed at night. The total hours of employment per week is, however, not a complete solution, there are so many other factors which cause overstrain in wartime. Long periods of traveling to and from work under uncomfortable conditions, lack of sufficient sleep, personal anxiety, shopping difficulties, and many other factors have to be considered. The nature of the work itself, degree of experience and individual capacity of the worker are also factors which could be properly assessed in the perfect system. Any system devised, however, can only cater for averages so as to maintain the health, strength, and production of the majority at the highest level. In wartime inevitably there will be strain to the individual, particularly to key-men, but it is the average that counts.

However, certain basic factors have to be attended to: these are, of course, limitation of hours of employment, measures to promote general health and welfare, and special measures for special occupations. Where there is definite exposure to cumulative poisons, limitation of the length of spells of employment involving such exposure and alternation of employment, so that risky work is alternated with other work not involving the risk, are supremely important, as for example where there is exposure to radioactive materials.

The fighting forces could not be maintained without medical, nursing, and welfare services, and it is well if one looks upon the industrial population as a different kind of fighting service requiring similar attention. The first thing to do was to extend greatly the provision of medical, nursing, and welfare services in industry and, at the same time, to secure that workers were not dependent for a satisfactory main meal on what they could bring to work from the family larder, but could obtain such a meal as an addition in the factory itself.

The Minister, therefore, issued two Orders, one the Factories (Medical and Welfare Services) Order, 1940, the other the Factories (Canteens) Order, 1940. The former enables the Chief Inspector of Factories to require factories on war work to install doctors, nurses, and welfare officers, the latter, in factories employing more than 250 persons, the establishment and maintenance of suitable canteens where hot meals can be purchased by the persons employed. Many of the larger works, of course, had these facilities in operation before the war, and they had proved their worth. The result of the Orders was that the great extension desired was obtained, and it is of some interest to note that voluntary acceptance of these requirements was almost unanimous and in no instance was it found necessary for an actual Order to be made under the Factories (Medical and Welfare Services) Order. A difficulty, however, was to find the whole and part-time doctors and the nursing personnel required. A further point which experience has shown is the value of medical and nursing services in a factory in aiding morale under "blitz" conditions. Particularly is this true of the factory nurse—a good nurse has a remarkable influence in many ways in a factory.

In order to fill these requirements the Minister found it necessary to provide introductory courses of instruction for doctors, nurses, and welfare officers in factory work. Universities, the Royal College of Nursing, and the Industrial Welfare Society, experienced doctors and nurses from factories, and members of the department all coöperated in giving short and practical instruction, so that these officers could function with the minimum delay.

It should be observed that the function of Works Medical Officers under the Order is not to give treatment such as the worker may obtain from his own doctor, but to give such advice as will

aid in keeping the worker fit and insure him obtaining appropriate treatment quickly when required; he should study working conditions in the factory so that a high standard of hygiene, first aid, etc., is achieved and maintained, and act as a liaison officer between the factory and the various health services, including the worker's own doctor and the Medical Inspector of Factories. The Works Medical Officer must, of course, maintain a completely impartial attitude so that he obtains and retains the confidence of all sections in the works. Similarly, the provision of canteens on a very large scale in factories proved to be a great stabilizing influence and is one of the most important wartime measures in maintaining health so far in operation.

The results obtained to date are that about 96 per cent of the factories employing over 250 persons have canteen facilities and the workers are thus able to get a substantial midday meal apart from their normal rations. This has been the method adopted by my country to make extra rations available to the industrial workers and can be contrasted with the German method of extra controlled rations for their heavy workers. It is a fact that the health of our industrial workers is better than in peacetime and I think this can be put down to the fact that additional employment and our rationing scheme have made for a better distribution of our food among the poorer sections of the community, and our canteens have provided for the industrial worker the extra food he must have for sustained effort. In the smallest factories where canteen facilities cannot be provided individually or by arrangement with adjoining factories, the use of the British Restaurants—similar canteen facilities by the Ministry of Food—local authorities for the force generally—fills the schemes.

In these ways the

of the factory population for maintenance of health and welfare have been catered for, and the system insures that special needs of a factory, say after bombing, are dealt with immediately.

Other general features to which reference should be made are the effects of substitution of women for men in industry and the age distribution of the industrial population. From the outset it was obvious that the most complete substitution possible of women for men was essential, and this was tackled by the Minister by registration of women, grading them by means of interview and allocating them to work for which they were most suited, and wherever possible to work for which they expressed preference. In addition very large numbers of volunteers were recruited. At the same time, by means of application of Essential Work Orders, the haphazard shifting of individuals from job to job was prevented. This stabilized experienced labor and permitted a rapid building up on these cadres.

It is obvious that now we have nearly reached the limit of conscription of men and women into the war effort. Part-time in industry will provide some further addition by means of employment of women, who have other inescapable duties.

The cheerful acceptance by women of all classes of these measures, or rather, I would say, the tremendous impetus given by women themselves to this movement is remarkable; not only that, but their adaptability and acceptance of responsibility is outstanding. Women are now engaged on work for which hitherto there has been no precedent and the substitution of women for men is still proceeding. Naturally enough this substitution casts considerable additional duties upon the Inspectorate, since many special measures have to be taken. Fortunately the department itself had been a pioneer for many years in this respect and had a nucleus of women inspectors

of some 30 per cent of its strength long before the war. These women inspectors had already proved themselves to be of equal capacity with the men and, of course, were specially experienced in the problems of women labor. The number of women inspectors has been increased since the war and the work they do both in the general work of the department and regarding the special requirements for women labor is invaluable.

A continuing anxiety to the Medical Section of the Inspectorate has been the possibility of special physical strains to women, resulting from their work in heavy occupations. Every alleged case or hint of such injury which has come to our notice—and as I mentioned before there is little of importance that does not come to our notice through some channel or another—has been carefully followed up, and so far we have no evidence to support suggestions that the work they are doing has caused damage in this way.

Much depends on the methods by which inexperienced women are introduced into industry. The best method, whether it be a light or a heavy industry, is by way of comparatively slow infiltration in the early stages. In the first place, where women have not been employed in the process before, it is necessary to select with great care a small number of intelligent women with personality and sincerity, capable of leadership—these will provide the supervisory grades of the future. The men then teach the women the job, paying special attention to the tricks of the trade associated with so many operations—for example, there is a special knack in taking off bricks from a brick press and this can be taught. Such knowledge means the difference between the likelihood of injury or not. Similar considerations apply to the making of drain pipes and many other occupations. When these key-women are thoroughly trained and experienced, then is the

time to introduce other women to be trained by them, and the substitution is complete. In fact, it seems that there is no limit to what women can do safely if they are properly trained, gradually attuned, and provided with suitable and safe clothing and decent amenities.

One cannot leave this subject of the general influences affecting health without referring to boredom. Boredom, as is generally agreed, is dangerous to health, safety, and production, but much can be done to relieve it. Suitable selected music, by means of radio has been provided by the BBC; concerts in the factories by ENSA (Entertainments National Services Association); dances, socials, sports, etc., encouraged by the Welfare Section, and experiments have been made in the use of broad color schemes in workrooms. More can be done with the object of making the worker feel that, whatever may be his difficulties owing to being away from his home and living possibly in uncongenial surroundings, his life at the factory is pleasant and supplies some of the amenities of which war has temporarily deprived him.

These upheavals in the national life have resulted in considerable changes in the age distribution of factory workers. So far as men are concerned in some industries there has been a large shift to the older age groups; thus in one industry, employing almost exclusively men at the moment, I found that approximately 50 per cent were aged between 30 and 50, and 50 per cent over 50, well over 10 per cent being 60 or over. I have not exact figures for the age distribution of the women in industry yet, but it is clear that in general here is the younger element (particularly under 25) of the factory population.

This distribution brings added responsibility to the medical services, and in this connection reference may be made to the increased incidence of

tuberculosis in young women. The increased possibilities in wartime of small epidemics in factories of diseases like diphtheria must not be overlooked. Obviously too, the strain on the older men is increased. I have no doubt that a cause of absenteeism among such men is physical inability to do the work to the capacity they did 20 years before.

Perhaps we might now touch briefly on the trends of specific occupational hazards. In general some have increased and some have diminished, as one would expect. Cases of lead poisoning, for example, have gone down because some of the main processes which caused lead poisoning have been shut down. Cases of gassing and dermatitis have greatly increased. The cases of gassing reported in accordance with the Factories Act have increased fourfold as compared with 1939, but the fatalities have increased in less proportion—30 per cent of the cases were due to carbon monoxide; 24 times as many cases of poisoning by nitrous fumes were notified in 1941 as compared with 1939, but there was only 1 death. The cases of gassing by trichlorethylene in 1941 were over 12 times as many as in 1938. In fact, almost every source of gassing in industry has produced an increased number of cases of poisoning.

Cases of toxic jaundice due to TNT are an interesting and important study. During the 13 months from July, 1916, to July, 1917, inclusive, the cases of toxic jaundice notified totalled 308, with 79 deaths. For the corresponding months of 1941–1942 there were 37 cases with 10 deaths. The reduction is, I think you will agree, astounding, and it is not due to a decreased population at risk. To what then is the improvement due? Partly it is due to improved conditions and precautions as compared with those in existence at the end of the last war, and these are still being improved, but this does not wholly answer the question. One can only surmise

that TNT is merely a precipitating factor in the production of toxic jaundice. What then is the primary factor?—constitutional perhaps. In any case it may be that a healthier population is the answer, and in this connection much credit must go to the Ministry of Food for having planned and secured a more complete and balanced diet than was possible in the last war.

Dermatitis is not compulsorily notifiable under the Factories Act, but the voluntarily reported cases are some measure of its incidence; in 1938, 2,195 cases were reported, while last year the number had gone up to 7,291—over 3 times as many. A third of these cases were in the chemical industry, including the manufacture and handling of explosives. Another large increase was associated with the engineering industry, much of it being due to oil. Dermatitis is an insistent problem because, although it is not so serious in its effects on health, it is a strain on production and the tendency to recurrence is a weighty factor. Some of the most potent dermatitis producers are found among the range of explosives, tetryl being a good example. An interesting feature about tetryl dermatitis is that, starting with a fresh population at risk, the peak in the number of the ensuing cases of dermatitis will occur toward the end of the second week of employment. It does appear that there are a certain proportion of extreme susceptibles to tetryl, and these have to be transferred to other occupations.

On the other hand, care will have to be taken to avoid wholesale transference because of dermatitis, for very obvious reasons. It seems that if workers do not develop dermatitis within the first fortnight from tetryl, they should not do so. Subsequently, if their health is maintained and the ordinary preventive measures are not only adopted but enforced, all should go well. The prime essential, as you

will agree, is thorough washing—which means actual supervision of each worker to see that this is done. It seems probable, too, that wherever possible workers with dermatitis should be kept at the work while under treatment, rather than put off and possibly become so sensitized that they can never go back to the dermatitis producing work.

The use of barrier substances, of course, has its place, but these cannot be in any sense a substitute for washing. A good deal of work is being done in my country on barrier substances, and it will be well if some standardization of suitable compositions can be achieved. Both our own department and the Ministry of Supply are to have the help of a consultative panel of dermatologists, which will help materially with the solution of these problems.

LUMINIZING

The use of radioactive substances in paints for painting instruments for aircraft and for some other purposes have caused us much thought for many years. With the expansion of this work since the outbreak of war and the rapid introduction of labor into this process, it has been considered necessary to devise and put into force a special Order embodying regulations of a preventive character. These are very strict and among other things limit the hours of employment in luminizing; prescribe special rooms for this work; properly designed benches with smooth surfaces; smooth floors; local exhaust ventilation; applicators, not brushes; glass screens between the worker and the work; protective clothing and protection of the stock of luminous compound; periodic medical examination and strict rules regarding washing; periodic blood examinations are carried out.

No illness of serious character which could be ascribed to this work has been found yet, but one or two cases with

burns have been noted and suspended, as also some workers with slight changes in the white cell counts, which may be suggestive. We have had to keep a lookout to prevent these processes being done by outworkers in their own homes.

FIRST AID ARRANGEMENTS

An important matter which has had to be kept in mind constantly has been first aid arrangements. Our proximity to enemy occupied bases has necessitated not only general tightening up of first aid arrangements in factories, but also a great expansion in trained personnel. Arrangements have had to be made to cope not only with day-to-day matters, but also with casualties due to enemy action. Moreover, the possibility that the enemy may use gas at any time has considerably complicated the situation.

The idea now is to concentrate all medical and first aid arrangements both for day-to-day and air-raid conditions in a single combined protected first aid post and ambulance room. Then if an "alert" occurs there is no transference from peacetime ambulance room to war-time first aid post, which has obvious operational advantages.

You will see that I have endeavored

to survey generally the reaction of my country to the demands the war has made on the human machine in industry; the difficulties we have encountered and the principles we are following in sustaining the health, safety, and welfare of the industrial army.

There is much more I would have liked to have discussed with you, such as the prevention of accidents, a problem of enhanced moment when the industrial population is expanded so rapidly. Perhaps, however, I might refer you to the *Annual Report of the Chief Inspector of Factories* for last year which has just been published.

At no time in our history has the individual, however he be employed, given himself to the national effort with such enthusiasm and devotion. We believe that much that we have evolved in the stress of war can be a permanent contribution to the well-being of those in industry, and this knowledge is an added spur to constructive planning in the bitter present, so that when the peace we fight for is with us, the united achievements of our two nations in occupational medicine and hygiene will be profound factors in the betterment of the human race.

War and the Health Department^{*}

A. Across the Nation

CHARLES P. TAFT

*Assistant Director, Office of Defense Health and Welfare Service,
Washington, D. C.*

IN the late summer of 1940 it was evident that the national defense program would place an abnormal strain on hundreds of communities. Military camps and large war industries were established in many undeveloped regions where health and sanitation facilities were of the most rudimentary kind. This presented a health hazard to the troops, for soldiers spend much of their time outside the camp boundaries. With regard to war industries, the hazard was equally great, for in today's warfare an unflinching service of supply is essential to military success. Conditions which jeopardize the health and productivity of war workers are a direct threat to national security.

In larger and more developed communities the situation was somewhat better. Modern facilities were at hand which provided reasonably adequate service for the normal population. Once the impact of the defense boom made itself felt, however, existing plant and equipment were no longer sufficient. This health situation was one factor in these communities that led the President to create the Office of Defense Health and Welfare Services under Paul V. McNutt.

Many rural areas, as well as small towns and cities, were literally swamped with construction workers who came to

erect cantonments, airfields, munition factories, and war production plants. Sudden population increases of 100 per cent were not uncommon, and in some instances communities swelled to ten times their normal size in a period of a few months. Unfortunately, the construction companies and sometimes the army failed to meet the need for supplying their workers with temporary housing, basic sanitary protection, and medical care. Trailer camps and shack towns began to dot the landscape. Doctors' offices and hospitals were soon severely overcrowded. Water supplies were threatened with exhaustion and sewage systems with breakdown. That is, assuming that there were hospitals, public water supplies, and sanitary sewerage—which often was not the case. As the construction period neared its end, soldiers or war workers arrived to man the new camps and factories. Many of them brought their families. A horde of others, service workers and camp followers of every description, also appeared on the scene, most of them entirely legitimate.

With varying degrees of intensity, this was the situation in several hundred communities. In general the picture was one of local congestion and disruption arising out of the national crisis. Not only was the problem national in origin, but its repercussions were nation-wide. Every one of the affected areas was a vital battle station in the conflict then moving closer to

^{*} Presented before a General Session of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

our shores. At that time few realized how close it was.

Because of the nature of the problem, and because local resources were usually inadequate to the task of solving it, federal aid was imperative. Fortunately one major agency of the federal government was on the job and collected fairly accurate data upon which to gauge the health needs of both individual communities and the nation as a whole. In the fall of 1940 the U. S. Public Health Service began a systematic series of reconnaissance surveys in vital defense areas. Teams of medical officers and sanitary engineers of the Service visited the areas, made a complete inventory of existing health and sanitation facilities, and estimated the types and amount of additional facilities required to care for the anticipated influx of population. The Service began expanding its grants for service by the states and localities. In many cases the local response and the community sense of responsibility were splendid. The state health departments in many states, and frequently the governors themselves, assumed leadership. The Public Health Service made lease-lend personnel available in especially needy areas. The figures showing the increase are impressive. Health units have increased by 415, or 74 per cent, and the counties served by 1,067, or 140 per cent.

But personnel was not enough; sewers and water lines were needed, quarters for the personnel, and hospitals for the normal proportion of sick. The little places and some big ones had exhausted their own resources, so in January, 1941, the President asked Congress to set up a program for grants-in-aid for facilities. In June, 1941, this federal aid for construction was made available through enactment of public law 137, commonly referred to as the Community Facilities Act. This is title II of the Lanham Act for war housing. The original appropriation provided \$150,000,000 in federal

funds to aid in the construction of needed public works, including health and sanitation installation, in communities where increased populations due to military or war industry developments imposed an excessive strain on existing facilities, and the community did not have the funds to pay for them. Later the amount available was increased by an additional \$150,000,000. The program thus launched was placed by Congress under the administration of the Federal Works Agency. Priorities will limit actual construction of schools, hospitals, sanitary installation, and recreation buildings to about \$150,000,000. Under the instructions of the President, the U. S. Public Health Service as one of the technical agencies of the government, undertook to investigate and determine the defense-connected need for all proposed hospital and sanitation projects, and to certify to the Federal Works Administrator projects which could be constructed with propriety under the terms of the Act.

It was inevitable that difficulties and delays should be experienced in a program of such scope in a time of crisis. In the first place, unprecedented demands had already been made on the construction industry by army cantonments and war industry plants. Moreover, there was considerable misunderstanding as to the kinds of projects contemplated by the Act. Many communities failed to recognize that this was to meet new war emergencies, not to remedy long standing deficiencies. It was natural for each community to press its own claims, but pretentious installations for the coming generation could not be permitted and the money had to be distributed where it would do the most good. Applications were filed for projects which bore little relation to the defense program and the total of askings ran to \$1,200,000,000.

In some cases applications for projects were filed in anticipation of needs which

did not materialize. Difficulty was often experienced in reaching an agreement with the local sponsor about its share of the cost, for many places were doubtful whether the boom would continue after the war, when they would still be paying. Some like Norfolk, Va., had been burned that way after the last war. In some localities there was no political unit with legal authority to sponsor a project or to pay for any part.

After bombs fell on Pearl Harbor many readjustments were necessary. Materials were short before that, but after December 7 it became worse. Projects had to be restudied and plans altered so as to strip critical materials.

Temporary construction took the place of permanent, and many projects had to be scaled down. This naturally affected the willingness of localities to contribute and a new basis for financing had to be worked out. Transportation, or rather its growing limitations for want of rubber, had serious effects. Housing projects had to be moved closer to bus lines or closer to factories. This meant re-study and re-location of the various utilities projects that served the houses. Moving the housing projects near the plants reduced the need for facilities in nearby towns.

In summary, during the fiscal year ending June 30, 1942, 4,468 applications were received by the Federal Works Agency. Of this number, 547 were for sewers and sewage treatment plants, 538 for water works, 567 for hospitals and additions, and 212 for health centers. The amount asked was \$140,000,000 from the government, with \$28,000,000 offered by the communities. That was the expectation if materials had been available—the actual results had to be different.

On August 1, 1942, a total of 206 water works and sewerage projects and 74 hospital and health center projects were under construction and were approximately 40 per cent completed. The

estimated total cost of these projects is about \$68,000,000.

As you can see, there remains a balance of considerable size from the Lanham appropriation. This appropriation has been considered available for grants for maintenance and operation, nearly all of which went for additional school teachers during the first year. There is some feeling now that this balance should be used for greatly expanded local services in the health, recreation, and welfare fields, and of course the needs are great. But several warning notes need to be sounded.

It is clear that the intent of Congress was primarily to provide facilities and not services. I gave the detailed testimony upon which the first appropriation was based and it showed only about \$18,000,000 for operation, mostly for schools, out of a total estimate of about \$275,000,000.

A second question arises when funds are offered to the states as in this case paralleling exactly those which Congress has otherwise provided, and has limited by certain conditions, such as auditing, civil service, etc., and which Congress has assigned for administration to other technical agencies of government.

Furthermore, all existing grant programs are through the states, not to localities direct—that is not only in harmony with the general pattern of our government but it has been adopted as the definite policy of government, applying to all grants administered through the Federal Security Agency and others so far as I know.

This general health and sanitation program has some interesting sidelights. The shortage of doctors, nurses, and other trained professional personnel is its most serious handicap. So far as doctors are concerned we are approaching the point where the army will have to work out a system under which their tables of organization will not actually be filled until their units approach the

front line action that requires that number of doctors. For they cannot themselves afford the serious depletion of man power in production and of morale on the home front created inevitably by the lack of at least minimum medical service. Only 3 soldiers in 7 ever reach the front.

The same comment applies to nurses, but here it is easier to speed up training processes in time to produce results in this war. That requires a greatly stepped up recruitment of students. I would note in passing that you will not get them unless better pay is offered to compete with war industry.

And it means further the increase of non-professional assistants, both in hospitals and in the public health field. Our hospital ratio of aides to nurses now is 1 to 1.8, compared to 4 aides in England to 1 nurse. You in the public health service will have to expand homemaker service that enables the visiting nurse to carry an even greater load.

There is even the possibility of a nurse supply board like procurement and assignment.

Do not forget industrial medicine. Our office is being asked by the War Manpower Commission to do a coordination job in the field of health and welfare within the plants, and we are counting on the full cooperation of both the Department of Labor and the National Safety Council. Here, too, the skilled personnel is rapidly being drained off, while the accident rate goes up and absenteeism increases. In a couple of months our office should be able to give a total picture, and it will not be good enough, for many if not most of the small plants and many of those rapidly expanded without prewar experience in this field, do not know how. But the government services, again working through the states, can and must be expanded to get the job done. It will be economy in man power and money in the end.

The venereal disease program has made great strides in the places that affect soldiers and sailors. Delays in providing quarantine facilities are, I trust, now overcome. It is mainly an educational problem. Army and Navy officers in the line and even in the Medical Corps needed to learn, and a new group of more than 130 specially trained venereal disease officers are out in the field doing that within the services, while at the same time they improve the whole process of treatment and of relations with the civilian health departments in case finding, etc.

Even some health officers need education. Within the last week I have heard of one state and one local health officer who say that all this noise about syphilis is an exaggeration. The state man said that it will not get to the "mental" state before the soldier gets to the front and perhaps gets shot anyway, so there is no need for all this propaganda. The local official said that the Selective Service examination rate in his city did not mean anything because it must have been acquired outside the city anyway.

That kind of attitude reflects the need for the education of the medical profession itself, and you will have to do that by vigorous campaign, not by incidental absorption. They will absorb the truth eventually before they die, most of them, but that takes too long.

Then police and judges and prosecutors need to know a lot more. Our social protection section is working with the International Association of Chiefs of Police and with the American and state bar associations. Professional backing in these fields is just as necessary as in the medical field. These law enforcement officials have just as erroneous ideas, many of them, about prostitutes and how to regulate them, and they are just as intelligent in their cooperation when they learn as the most experienced health officer.

Always at the end and at the begin-

ning we have the public, the leading citizen, the man in the street who has to have the story in his own language, and who must have a chance to learn in order to reach our goal, the elimination of venereal disease as a health menace in war and in peace.

In my book, syphilis and gonorrhea are epidemics, whether that is the right medical term or not, but there are many others. You in the health departments under the outstanding leadership of the Public Health Service and Dr. Parran are the front line of protection and you cannot fail. We cannot afford another 1918 influenza epidemic or anything like it. So when someone tells you that even the personnel and facilities of the minimal character which we can be allowed under military priorities are not necessary, you fight and we will fight with

you. We cannot allow a single hole in the dike if we are to win this war.

The whole program has required a high degree of coöperation between federal, state and local health agencies, and that must continue. I am sure that health officers and agencies appreciate the significance of this program as the foundation of national security. Yet we are all aware that every facility which might be desirable cannot be provided during the trying days ahead. It will be increasingly necessary to distinguish between what is indispensable and what is not. With intelligent selection of what we must have and vigorous promotion of our program of using those facilities we have a basis upon which the entire health organization of the country can and must be conducted for the period of the war and until victory.

War and the Health Department^{*}

B. In a Western County

WILTON L. HALVERSON, M.D., Dr.P.H., F.A.P.H.A.

Los Angeles County Health Officer, Los Angeles, Calif.

THE responsibility which now challenges every civil health organization and every health worker is the provision of the best possible health protection for the army behind the Army. To do this most effectively requires continuous, careful analysis of the rapidly developing war effort as it relates itself to the health programs of the various communities.

Governmental leaders, not all of whom are acquainted with the relative values of public health procedures, have in some cases brought pressure to establish new programs and in others to discontinue procedures of proven merit. Health administrators in most cases seek and welcome the viewpoint of governmental leaders not directly responsible for the health program. Leadership in shaping this specialized service to meet the ever changing needs can best be assumed however by the health administrator, provided he is well informed and alert. It is of paramount importance that the health program be related to the war effort, but it is also important that a sense of balance based on previous experience be maintained.

This discussion concerns War and the Health Department in a Western County. In some areas the county is a rudimentary organization. Our western counties on the contrary are strong governmental units. Los Angeles Coun-

ty's annual budget is over ninety million dollars. Over half a million of Los Angeles County's three million population live in unincorporated territory, some of which is as densely populated as its cities.

The Los Angeles metropolitan area is today one of the great industrial sections of the nation, with plants turning out planes, ships, guns, and scores of auxiliary products necessary to an army fighting a war to the finish and to a population which is now just beginning to learn the belt-tightening process necessary to victory. On the other hand, it is the richest agricultural county in the United States, producing dairy products, fruits, vegetables, grains, cattle, hogs, and other farm produce.

Health service in the unincorporated territory and in 40 of the 45 cities of the county, including a population of over one million, is administered by the Los Angeles County Health Department, which has a budget of approximately \$1 per capita served.

The program was well developed under the leadership of the late Dr. John L. Pomeroy, Health Officer of Los Angeles County for 27 years, until his death in March, 1941. Under his direction health facilities were brought to the neighborhood through the medium of modern health centers. Over a period of 20 years, 12 of these were constructed, equipped, and staffed. From these and many smaller stations the community is served.

^{*} Presented before a General Session of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

War has changed health department practices in Los Angeles County. Emergency protective services have been organized to meet the impact of attacks which the enemy is certain to use every effort to deliver. But more important, because of direct aid to the war effort, industrial hygiene, venereal disease control, tuberculosis control, nutrition, and other services have been emphasized.

EMERGENCY MEDICAL SERVICES

The long-range conservation programs developed by our local defense councils before the attack on Pearl Harbor were with this new phase of war placed in the background, and emergency protective services were given major consideration.

The health officers of Los Angeles City and Los Angeles County were named chiefs of emergency medical services in their respective jurisdictions. A joint medical advisory council with representation from medical, dental and nursing associations, hospitals, the Board of Education and the Red Cross was formed. Regular meetings are held for the purpose of coordinating procedure. Throughout the county approximately 200 casualty stations were set up by the Red Cross Chapters working with the chiefs of the emergency medical services. These were coordinated with the available community hospital facilities organized under a hospital committee.

The Los Angeles County Health Department has assigned to the emergency medical service on a full-time basis one trained district health officer as assistant chief of emergency medical service, one administrative assistant as procurement officer, and eight sanitary inspectors as field representatives. Two stenographers and two clerks complete the full-time personnel.

The health officer and other members of the department give various proportions of their time to the service. For instance, a carefully planned decontamination program is being organized under

the direction of the chief of the bureau of preventable diseases. This officer has worked out an authoritative outline of procedures for decontamination of persons. He has organized a course of instruction for the dentists of the community who have accepted the responsibility for leadership in this program. He has consulted with the senior gas officer in working out plans for decontamination units adapted to climatic conditions in this area.

The chiefs of the emergency medical services in our county working with the joint medical advisory council have carefully studied the available records of the experiences in those areas in Europe which have been subject to air attack. We have related these experiences to our community and have built a program which we believe will give the best protection possible when the need arises. This county with an area of over 4,000 square miles is larger than some states. Yet nearly all of its larger hospitals are located within a radius of 5 miles near the center of Los Angeles City. Each of the 45 cities has complete autonomy under charter and law. The Office of Civilian Defense in its plan of organization of local defense councils has recognized this autonomy, with the result that in our county there are 45 separate defense councils.

Because of the great distances of many of the target areas from hospitals, and because many of the smaller cities do not have hospitals equipped to care for air raid casualties, we have felt it necessary to organize self contained casualty stations equipped and manned by a staff of physicians, nurses, and first aid workers who live near these stations and who are assigned primarily to these stations rather than to hospitals. In the event of raids, casualties will be given primary care by field teams dispatched from casualty stations and sent to those hospitals having proper facilities and most accessible to the areas involved.

EMERGENCY SANITATION SERVICES

Los Angeles County has more than 400 public water systems. A working committee appointed by the defense councils, including representatives of the companies and the health departments, has developed schools for information on the preparation and use of emergency chlorinating equipment and on emergency operation. Thirty-seven emergency chlorinators have been purchased by water companies and health departments and are available for use where needed.

Mutual aid agreements between companies, both municipal and private, have been carefully worked out. Commanding officers of army units stationed in county health department territory rely on the water division of the department to recommend safe water supplies and to check routinely the water used by the various units.

The milk industry and the health departments through a representative emergency milk committee, early in December, 1941, circulated a questionnaire among all milk plants in the county. This provided information concerning the capacity operation, current operation, and the equipment available in each plant. Details concerning refrigeration, source of light, power and water supply are also tabulated. There is a complete list of all transport equipment, including delivery trucks of all types. The committee has secured a list of managers and alternates of each plant who may be reached when an emergency calls for the utilization of plant facilities. With the information available it will be possible in the event of the destruction or damage of one or more plants to divert the milk to others still able to function.

The committee has also compiled and disseminated plant protection information, and has fostered an effective plant protection program throughout the industry.

EMERGENCY HOUSING

War industries have increased the population of Los Angeles County by several hundred thousand. This has greatly taxed the available housing facilities. Federal housing projects administered through the Los Angeles City, Los Angeles County, and Federal Housing Authorities have provided during the past two years approximately 13,000 units. Private housing has made available approximately 57,000 additional units during the same period. The need, however, is far from met.

With the shortage of living space in the areas surrounding the large plants it has been necessary for some workers to travel great distances from home to plant. The average for the workers of one large plant a few months ago was 20 miles. The desirability of living near the plants has resulted in a tendency toward overcrowding in these areas. The State Housing Act and the County Sanitary Code have made it possible for the housing division of the department to prevent serious overcrowding and to maintain a reasonable standard of sanitation. It is unfortunately true, however, that thousands of the older houses, many of which are now occupied, do not approach the standards set by the Committee on the Hygiene of Housing, especially with regard to physiological and psychological needs.

With the approach of gas and rubber rationing, and considering the inadequacy of public transportation systems, the situation will become increasingly acute, and our health departments will find it increasingly difficult to maintain standards compatible with healthful living conditions.

INDUSTRIAL HYGIENE

Long before the attack on Pearl Harbor, tremendous industrial development demanded an effective industrial hygiene service. This activity of the department was born during wartime

and has been geared to fit the present needs of industry. Industrial plants in California, as in some other states, are inspected by several governmental agencies. Some of these agencies concern themselves with health hazards in industry, such as those resulting from the presence of toxic dusts, gases, vapors, and fumes.

One important facility has been lacking, namely, the resources of special equipment and trained men to make the highly technical studies necessary for actual evaluation of these hazards and provision of effective control measures. We have made good this shortage without introducing an additional inspection agency into the picture.

That this rather radical policy on the part of a public health department is workable is indicated by the fact that, within the short year during which our facilities have been in existence, we have been hard pressed to keep up with the demands. We find ourselves, therefore, in the unusual rôle of rendering scientific consulting service to such agencies as the State Industrial Accident Commission, insurance companies, plant management, and industrial physicians.

Two tremendous dividends of such a program are that no time is lost in looking for work, and, since the service is earnestly requested in the first place, the recommendations in which our studies culminate are carefully considered and used as a basis in the design of control measures.

COMMUNICABLE DISEASES

The control of acute communicable diseases has thus far presented no special problems. We have not as yet inaugurated or planned a routine typhoid immunization program, although there are those who advocate such a measure. Diphtheria and smallpox immunization were increased greatly over the preceding year.

Tuberculosis control is receiving spe-

cial emphasis because of the prospects of a long war with a consequent lowering of the economic status and a resultant increase in this disease. The tuberculosis associations of the county are strongly fostering case finding in industry. They have recently purchased on a coöperative basis a mobile 4 x 5 stereo photoroentgen unit which, when delivered, will be used exclusively for this purpose. Already the employees of several industrial plants have been checked with standard size film. One large aircraft factory is now, through its medical department, routinely x-raying all new employees, and another plant has a photoroentgen unit on order.

The health department, in addition to its regular case finding program, is making house-to-house surveys in low income areas. These surveys are at present the most fruitful source of new cases. Ten thousand x-rays uncovered 59 new active cases—almost 0.6 per cent—during the fiscal year 1941-1942. This work has been done largely with the photoroentgen units operated by the health department in its regular program.

Syphilis and gonorrhea control measures have also been emphasized. During the past year an increase of 36 per cent of new patients visited the department's 2,000 clinic sessions for diagnosis and treatment. An important increment to the venereal disease case load has been selective service registrants who are referred to us by the selective service boards through the State Board of Health, because of serologic tests for syphilis. We have thus far examined more than 1,100 such referrals. Each case receives a thorough study, which includes spinal fluid examination and cardiovascular x-rays. The clinical status of the selectee is thus determined, and many of these men are being rehabilitated for military duty. Familial and other contacts are examined.

Prostitution has been rigorously repressed by the law enforcement agencies

and an arrangement has been worked out so that all women arrested on morals charges and who are brought to the Los Angeles County Jail are placed under legal quarantine. These suspects are held—against bail—until blood tests, smears and cultures may be made. If venereal disease is found in an infectious stage, isolation is extended.

Since the task of venereal disease control in wartime is so vital a responsibility, it has been necessary to expand this service. Substantial assistance has been provided through federal funds. We are now preparing to embark upon a campaign of social hygiene education to be integrated with a general health education program and directed primarily toward workers in our local armament plants. More than 350,000 people are now employed in these plants in Los Angeles County. Most of these workers are young men and women who have never before received the bonanza wages of expanding industrialization. We feel that we have a responsibility to give to these workers the best health information available. Both management and labor have been included in the plans and have given wholehearted cooperation.

CHILD CARE

An important recent community development was the "Conference on Childhood and Youth in Wartime." This was planned by the Council of Social Agencies and jointly sponsored by the defense councils, the Board of Education and the coordinating council. The purpose was to focus attention on the importance of continuing support of public and private child and youth service agencies during the emergency. The meetings of the recent two day conference were crowded with enthusiastic participants. Problems relating to health, welfare, delinquency, work, the school, and a future program were seriously discussed by local and national experts

in the field. The opening luncheon and closing dinner sessions were attended by a 2,000 capacity crowd and many were turned away. The theater used for the general sessions was filled, and hundreds were forced to listen to proceedings by loud speaker in an adjoining hall. A series of carefully thought-out recommendations to improve the community health and welfare facilities for children was unanimously passed at the closing session, and a follow-up committee was commissioned to activate this Los Angeles Children's Charter. Already a health education program sponsored by the Council of Social Agencies and participated in by every health agency is being planned.

NUTRITION

The health officers of Los Angeles County and Los Angeles City have led in a county-wide nutrition program. During the past year almost 200 group leaders have received technical instruction. This fall these leaders are conducting nutrition discussion groups under the auspices of parent-teacher associations, schools and other groups, using standard materials made available to them. The Los Angeles Chapter of the American Red Cross, with excellent leadership, has alone given nutrition courses to over 18,000 women.

The committee sponsored a "lunch box derby" which was organized and arranged by the leading house furnishings establishments of Los Angeles. As a result of good publicity superimposed on timely interest, thousands of women inspected lunches prepared by various commercial organizations. These lunches were judged by nutritionists as to food value. The news releases following the exhibit gave scientific information of general interest on how a good lunch should be prepared. The large metropolitan newspapers are keeping this interest alive by frequent special articles and layouts.

Health workers now have the greatest opportunity for service to our country and our fellow men that has ever faced us. Let us not fail to attack our problem courageously; let us not be swayed by personal or organizational considera-

tions; but may we place every energy and facility at our command where it will serve most effectively, to the end that this struggle upon which depends the survival of our civilization may be rapidly and successfully concluded.

The Resurvey of Graduate Nurses

A NATION-WIDE survey of graduate registered nurses is being undertaken January 1, 1943, by the U. S. Public Health Service at the request of the Subcommittee on Nursing of the Office of Defense Health and Welfare Services. Every effort will be made to obtain an accurate and complete record of the available nurse power of the country.

The questionnaire being sent to nurses for the survey carries a statement by Paul V. McNutt, Chairman of the War Manpower Commission to the effect that, "The nursing shortage is urgent, both at home and on the fighting fronts. Today there is only one place for the graduate registered nurse to be—that is, on active nursing duty.

"That means all nurses. Whether married or single, whether eligible for service with the armed forces or retired, there is a place for every nurse. Lives may depend upon how quickly you respond to this call."

Return post cards have been provided by the U. S. Public Health Service and will be distributed in the states by the State Agent for the Inventory, appointed for this purpose. Local Nursing Councils for War Service and District Nursing Associations will coöperate in locating graduate nurses in their communities. The completed questionnaires will be retained in local areas, tabulations of data being sent to the State Agents, who, in turn, will send a complete tabulation for the state as a whole

to the U. S. Public Health Service in Washington, D. C.

The nation is facing a critical nursing shortage due to the needs of the armed services, the inequitable distribution of available nurse power, and to expanding the requirements of industry, public health, and hospital services.

The survey being undertaken should contribute markedly to the solution of some of these problems. It will enable the Nursing Councils for War Service to analyze their resources and needs, to locate nurses available for military service, to determine which nurses are holding strategic positions essential to the war effort, to plan for the part-time use of married nurses, to secure volunteers for emergency medical services or for Red Cross classes, and to relieve some of the inequalities in distribution. Nationally, it will provide a picture of the country's nursing resources which should form a basis for an estimate of the number of student nurses needed, the number and type of auxiliary workers to be prepared, and the ratio of nurses to population available, when distribution plans may be effectuated.

It is essential that every graduate nurse, married or single, active or inactive, fill out a survey and return it to her State Agent at once. Nurses who have not received a card may secure one from the state Nursing Council for War Service or the State Nurse's Association.

War and the Health Department^{*}

C. In an Eastern City

ALFRED L. BURGDORF, M.D., F.A.P.H.A.

Health Officer, Hartford, Conn.

CATASTROPHES of any kind, be they war, flood, epidemic, hurricane, or any other disturbance of the elements, have always dramatically and sometimes painfully, demonstrated that a well organized official health agency is of inestimable value to a community. Such events frequently accomplish what no survey has been able to do—the laying bare of unrecognized strengths or weaknesses, as the case may be. Each community might well ask itself even at this late date, “Do we have adequate health protection?” Perhaps the question has already been partially answered. The ensuing weeks, months, and years of this present world struggle will further clarify our positions.

It is realized that no two health units are the same, that they are not confronted with identical problems, and that they do not have the same resources with which to meet them. It is further realized that different sections of the country have radically different political backgrounds and patterns. The remarks that I shall make are strongly colored by the conditions, institutions and political makeup existent in the New England States from which I come.

There is one thing, however, common to us all and that is that our organizations are being tremendously influenced by the war effort and that we are in

turn trying our best to influence that war effort.

We are being disrupted and it is not comfortable. If we have been complacent, we can no longer endure that state. Whether this disruption leads downward or upward will depend largely, I hope, on the effort we make to guide that disruption.

The administrator of a full-time professional health department is confronted with numerous problems, particularly if he is placed in an industrial area, and practically all of New England represents heavily industrialized communities. In the first place he is dealing with a new population both in numbers, background, and age distribution, and one that is continually shifting. The influx is largely made up of young industrial workers, many from rural areas, so that the immune/non-immune ratio established over a period of years is disturbed. Secondly, official population figures are not available so that calculated rates are always higher than the actual ones.

Furthermore, the community health facilities were not planned for such increased numbers, and in many instances even the small scheduled expansion of existing services is made impossible by decreasing personnel and priority regulations. Making extra provisions to cope with the extra, the unexpected and the unplanned for wartime expansion appears to be entirely remote.

^{*} Presented before a General Session of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

Take such a community and place it in housing that is inadequate in quantity both old and new; attempt to feed a large portion of it in public eating establishments manned by transient, inexperienced, and insufficient food handlers; entertain it through the many off-shifts of industry on a twenty-four hour basis with the old facilities; service it by the changing personnel of public service agencies; and the inevitable result is the magnification and multiplication of old problems.

In addition the difficulties encountered in attempting to maintain the sanitary conditions when the owner is held down by the Office of Price Administration and is reluctant to make improvements, and when the disgusted tenant is unable to vent his spleen by moving elsewhere because there is no elsewhere, add the finishing touches to a very difficult situation.

This brief picture of a community mobilized in an urban center for total war effort can be seen anywhere on the eastern coast, and undoubtedly throughout the land.

There is an old medical saw that says, "Once the diagnosis has been made, the treatment is easy." The diagnosis of many of our social ills has been established, and new ones are being made daily, but the treatment is not easy. The case is far from hopeless, however, and this consideration leads us to ask, "How are health departments meeting the present demands made upon them by their ailing communities?"

In the first place, they are budgeting their time and rationing their services. In the second place, they are devising new ways of doing old jobs, just as industry is finding new ways and new processes to turn out old products. In places where specialized inspectors were overlapping territory with other specialized inspectors from the same office, generalized health inspection service is being set up. This means

greater in-service training, not some day, but now. The program being polished up for a launching some day must be put into action today.

Where nursing service was largely on a home visiting basis with a good deal of individual teaching, group conferences are being set up to conserve nurse hours by bringing the people to the nurse. Where immunization promotion was carried on in special groups through purely educational methods, the more rapid direct demonstration method is being employed.

Duties performed and responsibilities held by the heads of bureaus are being delegated to other members of the organization. Programs with long-range objectives, but with insufficient immediate return, like certain tuberculin testing programs, are being dropped for the duration. Other programs, where evidence was accumulating that they had little mass value, such as Schick testing in the younger age groups, are also being dropped. New office procedures are being developed with greater use of punch card mechanics.

In this connection it is frequently possible to double up with some other governmental agency and make use of partially idle equipment. Especially is such reorganization of office procedure imperative in the bureaus of vital statistics where demands for copies of vital records have bounded to unthought of heights. The unnecessary tabulation and filing of a lot of non-pertinent material against the day when it may possibly be used for some nebulous study that was conceived thirty years ago and has now become not only hazy, but actually fog-bound, has suddenly ceased. Such reorganization of the health department activities is basic to any contribution to the production front.

There are, however, other ways beside improving our regular routine duties in which health departments can be of service. In this connection it is an op-

portune time in which to examine our relationship to the community at large in which we work.

We have come to subscribe to the tenet that the health department should be the natural leader of the community in the field of health. In war this has special significance. Merely saying so, however, does not make it so. Leadership demands first an understanding of all health problems in any community, and, secondly, a desire to know as far as possible what every other agency is contributing to the entire picture. To do this the health department personnel must identify itself *with* and show a real interest *in* every community health enterprise.

No longer can we sit behind our administrative desks cloaked with the authority and prestige that has come to us out of the past. The demands of *today* are not those of yesterday, whether it be in the field of restaurant sanitation or medical rationing. If we have not been consulted about a new community health problem, it may possibly be due to lack of appreciation by the other fellow for the importance of our position, but more likely it is due to the fact that we have not been too helpful in some previous situation, and have lost face.

Community health planning in its broader sense, whether it be a rehabilitation program in a struggling private agency, the need for federal funds for additional beds in the local hospital, whether it be an open sewer near a temporary housing project, the need for day nurseries for war working mothers, a feeding program in a settlement house, funds for the training of nurses and physiotherapists in the Kenny treatment, war programs for the medical society meetings—all have bearing on the health of our communities, and the health department should be actively helpful whenever it can.

Many private agencies with well established programs have felt it necessary

to make revisions in their activities in order to gear their efforts most effectively to the national war needs. Many can be influenced to contribute to the health program. The close contact that exists between the health department and the people means ability to interpret community health needs into such agency planning.

Basic to community health planning is a complete picture of local health resources. In times of peace there may be a certain amount of competitive spirit in the field of health and medical service which falls away in war time and co-operative use of many facilities is much more easily consummated. We need now more than ever a detailed listing of what health facilities the community has to offer.

If this is done, we shall all undoubtedly realize that we were not making the maximum use of our available services, that not enough persons were aware of the existence of these facilities. Several communities have pooled such detailed information of many agencies so that all concerned had a complete picture of such services.

The public is more health-minded at the present time than ever before in our generation. Publicity of the results of Selective Service examination, the national nutrition program, more widespread preemployment health examinations, mass health surveys, Workmen's Compensation legislation, publicity of the National Infantile Paralysis Foundation, and many others have made health a news item.

The daily increasing number of articles in magazines and newspapers on health is a token of that change. The people are prepared to make greater provisions for public health—now in time of national emergency it may be possible to overcome public apathy in regard to the need for complete protection of its milk supply; now is the time to get the public clinics out of town hall

basements or other dark and dingy quarters and improve the quality of treatment rendered to the medically indigent; now is the time to improve the sanitary quality of our public water supply when a "break" may mean a calamitous breakdown in production.

The public is most sensitive to the war-associated problems involved in syphilis and tuberculosis. They know that a nation in arms has always experienced increases in these two diseases. We are anxious to increase and expand our control efforts in these two fields and the public expects it.

In tuberculosis the small film, the 8" x 10" or the 35 mm. makes possible greater case finding programs by mass x-raying of the now gradually disappearing lower economic group, and groups where high incidence of the disease occurs.

In syphilis control more and more persons can find their way to treatment with the private physicians. This calls for perfecting and extending our activities into the doctor's office so that we can hold the patient there and carry on the same control program with the co-operation of each practising physician treating the disease. This program is more difficult and calls for maximum tact and perseverance on the part of the field worker. A real bilateral relationship between doctor and health department must be developed if the control of syphilis is to reach the heights demanded by our disorganized social life.

The establishment of the Office of Civilian Defense with its state and local defense councils has brought the health department new contacts with old and new agencies. The office of Civilian Defense has taken it for granted that health departments would assume responsibility for its classic fields—water supplies, sanitation, communicable diseases. On the other hand, in the organization of large groups of volunteers for the various services, the health depart-

ments have been extremely helpful in aiding to lay the groundwork for such organization by contributing what information they had in making population studies, in zoning the cities, and in some instances developing the entire program of emergency medical services in coöperation with hospitals, medical societies, and volunteer groups.

Wherever this has been done, the planning of services has in most instances been more closely tailored to the needs of the community, and has taken into consideration the peculiarities of each municipality. Here there has been an opportunity for the health department to point the way for amicable and harmonious coöperative planning and action of the American Red Cross, the Office of Civilian Defense, social welfare groups, and official governmental agencies. It has benefited the taxpayer too in that under the pressure of the Pearl Harbor aftermath, unnecessary expenditures were kept to a minimum, and every attempt was made to utilize existing facilities and equipment. Under the general leadership of local defense councils, it has been possible to assist hospitals in developing and recruiting emergency hospital auxiliaries, as well as to stimulate and help in the planning for hospital evacuation.

We can also profit from the services of some of the Office of Civilian Defense activities. I need merely mention that air raid wardens are in a position to give us sorely needed assistance in making an up-to-date census of our rapidly shifting populations. The necessity of having more accurate figures on which to compute rates for our vital phenomena is a real one.

A particular concern of health departments is the need for coördination of programs and activities of one political subdivision with contiguous ones. This need is already very apparent and has assumed greater urgency because of the war activity. This is particularly

true where full-time health services are in operation in one city or town and part-time service in another, or where there are smaller units, all of which operate under a part-time health department system. Where large industries are operating and drawing the large part of population from many dissimilarly health-serviced towns into their plants, we have population aggregates enjoying excellent health protection for eight hours of each day, and poor or mediocre health service during the remaining sixteen hours. It would appear that the establishment of district health divisions, explored in times of peace, is far more urgent as a result of the many population cross currents resulting from the war effort.

Under this arrangement adequate

health protection for the migrant and suburban industrial worker would approach reality. The grouping of such district health services on the basis of shopping centers should not present too great difficulties since the need for them already existed, and now has become more than evident.

Never before has it been so necessary for us continually to evaluate our position and analyze what we are doing in the light of constantly changing conditions. We must be ready as never before to keep our programs fluid enough so that they can meet new and unexpected needs as they arise—alert also to detect the beginnings of the post-war problems so that prevention, the essence of all public health philosophy, may be the first step in the reconstruction period.

Basic Criteria for Qualified Leadership in the Environmental Sanitation Program*

FELIX J. UNDERWOOD, M.D., F.A.P.H.A.

Executive Officer, Mississippi State Board of Health, Jackson, Miss.

ALTHOUGH public health activities have expanded in many directions in recent years, embracing new and helpful developments as science progressed, sanitation continues to be one of the basic functions of the health program. In fact, one of the outstanding contributions of all times to mankind's security and comfort has been the environmental control of disease which the application of scientific sanitary principles has made possible. Looking back over the years of successive achievements in this field, we feel a surge of pride. However, during this evolutionary period, it must be admitted that we have had our shortcomings too, and in spite of our successes certain deficiencies have cropped up from time to time in the sanitation program which curtailed its effectiveness. It seems fitting, therefore, that we pause long enough to take stock of present-day objectives and organization with a view to determining how we might best achieve the desired goals of today's environmental sanitation program.

The type of organization through which we must work is a vital consideration. No matter how minor or routine actual sanitation activities may be, it is apparent that their conception and

general guidance require both medical and engineering ability of a high order. To execute efficiently the numerous duties for which he is primarily responsible, the public health engineer must possess certain basic qualifications. Likewise, definite principles of administration must be developed if the sanitation program is to function properly. The health officer's recognition of these facts, together with his full coöperation in formulating policies to achieve the ends desired, is one of the basic criteria for qualified leadership.

It appears that the basic criteria for qualified leadership in the environmental sanitation program resolve themselves into four fundamental elements:

1. Basic training and experience of the public health engineering personnel.
2. A clear understanding of the nature and scope of public health engineering by those charged with administering any part of the sanitation program.
3. Proper training and coördination of all personnel engaged in the environmental sanitation program.
4. A clear understanding by public health administrators of the function of the public health engineer with respect to administration and supervision of the sanitation program. Much confusion now existing in both the administration and performance of the local sanitation program could be eliminated if a proper realization of professional supervision could be established.⁴

As to basic training, the Committee on Professional Education of the American Public Health Association, in a

* Presented before a Joint Session of the Health Officers and Engineering Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

report approved by the Governing Council October 5, 1937, pointed out that the engineer who adopts public health as a career should have general educational qualifications somewhat comparable to those of a physician entering the public health field. The importance of the qualifications which the committee outlined needs reemphasizing, in view of the fact that no leadership can be attained in the sanitation program unless its various functions are delegated to individuals thoroughly competent to carry them out. Not only must the administrative personnel be well educated and trained in the principles of public health engineering but it must be able to direct and supervise the activities of sub-professional personnel which most health departments find it necessary to employ in the interest of economy. To give assignments to these workers calling for engineering knowledge and experience they do not possess would certainly jeopardize the quality of leadership desired for an effective program. However, much can be added to the program if care is taken to allocate to those individuals duties commensurate with their ability, and if opportunities are given them for field experience under supervision. Leadership depends upon the proper utilization of supplementary workers and also upon auxiliary or outside agencies, with careful coordination of all activities into the entire sanitation program.

In view of the responsibility of the administrative personnel, it seems worth while to repeat here the subjects which the Committee on Professional Education of the American Public Health Association outlined as an essential part of the educational equipment of the public health engineer in addition to his purely engineering studies. They are:

1. *Biostatistics* sufficient to give a sound conception of the mass phenomena of disease, familiarity with methods of collecting, recording, and studying statistics on vital phe-

nomena, and ability to interpret the results of the analysis of such material.

2. General or theoretical *epidemiology*, including instruction in the collection, recording, analysis, and interpretation of epidemiological information regarding those diseases toward the prevention and control of which the public health engineer would be expected to contribute.

3. General *historical background of health administration* and a general knowledge of the organization and functions of the national, state, and local administrative units.

4. Fundamentals of common law.

5. *Sanitary biology* and instruction in *interpretation of laboratory reports* and methods of administration and operation of laboratories in connection with public health work.

6. *Food technology*, with particular reference to production and pasteurization of milk, and familiarity with methods of protection against such diseases as may be transmitted by foods.

7. *Entomology* as it applies to those insects which may be vectors in disease transmission and in methods of their control.

8. *Housing* with respect to health.

9. *Lighting, ventilation, and plumbing*, sufficient to give some knowledge of these subjects.

10. *Industrial sanitation*, particularly with reference to certain hazards, the correction of which is largely an engineering problem.

11. *Environmental sanitation* as it applies to rural areas and to recreational facilities.

With fundamental training in engineering in addition to a comprehensive knowledge of the subjects enumerated the public health engineer is prepared to make accurate analyses of environmental health problems and to work out effective methods of control; that is, of course, if with all his professional education he has developed a mind which is trained to meet individual problems in an original manner. No amount of knowledge gained can be considered an asset to the sanitation program if it is not forthcoming when needed or if it is not properly applied. Leadership calls for initiative and clear-cut objectives.

As one reflects upon the close relationship of the activities of the public health engineer to other units of the health organization, it becomes obvious

that there must be the best of supervision and direction from the central offices in order best to coördinate the activities of all health workers and to make for a unified program. This, as pointed out before, calls for a close working relationship on the part of the health officer and public health engineer, with a complete understanding on the part of both officials as to policies and methods to be pursued in solving the various problems which arise.

In the Report of the Committee on 'Coördination of Public Health Engineering Activities,'² in 1940, an attempt has been made to define more clearly the proper functions of public health engineers and other personnel in environmental sanitation, and to suggest methods for more effective coördination and supervision of activities. Under a section entitled, "Administration and Supervision," it is recommended that:

1. All public health engineering activities should be under the supervision of a competent public health engineer who should be directly responsible to the administrative health officer for all matters which affect their professional integrity.

2. The extent to which particular activities should be performed by technicians or other supplementary personnel and the details of administrative arrangement to provide for engineering supervision will depend upon the nature of the problem, the feasibility of specifying definite procedures, and the capabilities of individual workers.

3. The administration of state and local health departments should provide for consultation and interchanges of service and information so as to maintain coördination of the work of public health engineering divisions and of other administrative units.

Commenting upon this subject further, the report concluded:

In order to provide for effective supervision of all aspects of environmental sanitation, certain major administrative functions must be delegated by health officers to their directors of public health engineering divisions. Obviously these should include administration of the division office and the approval of stand-

ards and technics. Also they should include technical planning and supervision of all types of sanitation work, and appraisal of the qualifications, training facilities, and procedures of sanitation personnel. The assistance and influence of public health engineers should be further extended and utilized by consultations and joint services with other divisions. In this way the engineering aspects of the entire public health program can be adequately supervised without confusion or overlapping of administrative responsibility.

Without doubt, qualified leadership in the environmental sanitation program depends upon both technical ability and initiative in applying this ability in an effective manner. Public confidence, which can contribute tremendously to leadership, is often inspired by the manner in which local activities are carried out and by the attitudes and competency of those carrying on these activities. Consequently, it seems of the utmost importance that all workers manifest a spirit of appreciation for the objectives of the program and that they approach their particular assignments in a manner which will reflect credit upon their own efficiency and that of the health department.

The enforcement of the police power necessary to carry out the protective sanitary regulations is one item which calls for discretion and tactful handling. The worker who is wise will be able to cope with most cases with little or no friction. He will encounter difficulties from time to time, no doubt; especially if he has an apathetic public to deal with or runs into obstacles imposed by local political machinations. However, in most instances, he will be able to dispose of these matters without conflict, depending largely upon the policy and personnel of the local health department and upon some measure of individual ingenuity, common sense, and a knowledge of human relations. As a result of handling difficult situations competently, leadership in the sanitation program will be further strengthened.

There is no doubt but that the efficiency of the entire health program is judged in large measure by the quality of work performed by the public health engineering personnel, due to the intimate contact these individuals have with the general public. Therefore, at a time when so much depends upon the thoroughness of planning and carrying out of well rounded health programs, more attention than ever should be given the basic criteria for leadership in the environmental sanitation program.

While public health has reached a high state of achievement in recent years we have hardly begun to put to work the full knowledge which could liberate man further from the primitive and elementary bonds of ignorance, superstition, and disease. Think of what could be accomplished if all the defects of the physical community could be corrected! We are constantly urging as a preventive measure that individuals submit periodically to their physicians for a check-up and get all remediable defects corrected. Is it not just as important to subject the total physical surroundings to the same sort of rigid check-up by those expert in diagnosis in this field and possessing adequate knowledge to cope with the problems presented? The public health engineer's position in this respect parallels that of the physician. Of what

avail is it to see the physician several times a year if each time the individual goes back home to an environment which is a hazard to health?

As we survey conditions all around us, it is realized that there is yet a considerable job to be done—one that calls for teamwork and careful planning. Public health has met the challenges of the past and I am sure that those of us responsible for its functions today are eager and willing to put our shoulders to the wheel and to work unceasingly until we have achieved the goals we know are within reach.

"To live in health, to be free in spirit, and to pursue happiness through fellowship—these were and remain the objectives of American democracy. These are the values which now have been brought to the crucial test."³ With the improved equipment and advanced knowledge we have at our disposal today, I sincerely feel that public health will not be found lacking in the worth while accomplishments of this period or in meeting the demands of the future.

Responsibility of Local Health Authorities in the War Emergency*

JOSEPH W. MOUNTIN, M.D., F.A.P.H.A.

Assistant Surgeon General, States Relations Division, U. S. Public Health Service, Washington, D. C.

THE subject assigned to me for discussion, namely, "The Responsibility of Local Health Authorities in the War Emergency," carries with it the implication that all areas in the United States are served by some form of local health organization capable of accepting responsibility and exercising authority. According to this interpretation, it is assumed that full-fledged staffs of local public health workers wait only to be told what to do before springing into action.

This, I am sorry to say, is far from a true picture of the situation. In spite of considerable progress in recent years, no such comprehensive network of local health services exists. In extensive areas of the United States the exercise of local health functions is vested in political jurisdictions such as townships, boroughs, villages, and, in some instances, counties, in which the population consists of from a few hundred to a few thousand inhabitants. Such local subdivisions are in most instances nothing more than geographical fictions designed to fulfil the political requirements of the horse-and-buggy era. They bear no relationship to present community life, nor do they in any sense contain institutions or administrative units which meet the economic and social needs of the population. Like the human vermiform appendix, evolution has rendered them obsolete and functionally sterile.

In such vestigial jurisdictions legal health authority is often exercised by a person who devotes only a small part of his time to health functions. He may hold his position as health officer solely by virtue of the fact that he was elected town clerk or marshall, or he may have been appointed to the job. In either case his tenure of the position is based on no qualifications beyond his ability to secure and hold office. I have had occasion to make administrative surveys of such local governmental units and to tabulate the basic occupations of those charged with the fulfillment of health duties. It was astonishing to find what a wide range of human pursuits was covered—represented were farmers, undertakers, storekeepers, railroad employees, janitors, and barbers. Indeed, some of the incumbents were unable to place themselves in any occupational category, and naively listed themselves as "unemployed."

Obviously it is futile to attempt to discuss official responsibility or health program content in areas where health activities are in the hands of such inept types of organization. These organizations are not even keyed to meeting the needs of the community in normal times, and cannot be expected to function any better during a crisis. It is important that we recognize this basic deficiency before passing important responsibilities on to such agencies with no more than a wave of the hand.

The political map of this country, in

* Presented at the Third Pennsylvania Health Institute, Harrisburg, Pa., September 30, 1942.

so far as rural jurisdictions are concerned, was made for the most part by surveyors who thought in terms of rectangles and plotted the land before it was inhabited or developed. In settling the country, however, people were motivated by economic and social factors rather than by geometry. They chose to make their homes in places where the topography, soil, and material resources were suited to the gaining of a livelihood, and as a result community outlines developed which bore little or no relationship to political boundaries. As more speedy and convenient methods of transportation were perfected, the disparity between the social and the political unit became even more pronounced. Nevertheless, in many instances the public services designed to meet the people's needs continued to be administered within the arbitrarily imposed and outdated political framework.

The obvious remedy is to extend the jurisdictional limits of the administrative unit so that they will conform in general with the boundaries of the community to be served. When so extended the health organization has a rational basis for existence and a theater of operation in which it can be expected to achieve tangible results. Of course, certain difficulties are sure to be encountered in bringing about such changes, but they are by no means insuperable. There is nothing novel or revolutionary about such rearrangements; they have been resorted to time and time again in the course of our national development. The township, once the unit of all local government, is today nothing more than a symbol of local autonomy. As circumstances warranted, its functions passed into the hands of the counties or larger jurisdictions. Maintenance of the highways was once a duty of the local road district, but with the advent of the automobile the responsibility passed to the county, only to be assumed later by the state. Likewise, districts were formed

for the administration of water supplies, sewerage systems, educational facilities, mosquito control, and other functions which could not be carried out effectively by existing official units. It has also been demonstrated that boundaries can be altered and political entities regrouped when such an expedient serves political ends. Even the founding fathers of our Republic were adept in this practice, and as long ago as 1812 the word "gerrymandering" was coined to describe it.

Local public health agencies have lagged behind other branches of public service in adjusting their organizational structure to suit changing social conditions. It is now a question of determining how to accelerate the natural process of adaptation in order to meet an emergency situation.

The American Public Health Association, through its Committee on Administrative Practice, has recently formulated a provisional set of basic criteria for local health services. In its report the committee states that all population units or areas in the United States should be served by local health units which are directed by full-time medical health officers. In general such local units should serve a population of not less than 50,000 and not more than 250,000, except where one or more counties constitute a single health jurisdiction in a metropolitan region. The area served by one unit should not extend more than 40 miles in any direction from the headquarters office. The units so conceived may be single-county units, multiple-county units, or district units including a part but not all of one or more counties. The committee recommends that cities located within a county be served by an inclusive type of county or district health unit.

The report assumes that most services of a clinical nature will be performed by part-time medical personnel drawn from the local practising profession. It also

states that a unit should have not less than 1 nurse for each 5,000 of population; 1 sanitarian for each 25,000 to 35,000 population, with at least 1 member of the sanitation staff of engineer grade if the population is 50,000 or more; and a sufficient clerical force to keep records and leave the technical staff free for professional work.

The objection may be made that redrawing the health map on the basis of such principles is a highly theoretical procedure. This, however, is not so. Today, we cannot deny the immediate and practical value of any thoughtfully conceived effort to put on a rational basis the distribution of our nation's health services. The war has brought about a tremendous disruption in community life in hundreds of localities throughout the country. Health problems have been multiplied and magnified, whereas our resources for dealing with these problems have diminished. Shortages of many kinds of essential materials, and above all of personnel, are already crippling the inadequate services hitherto maintained. At the same time, all available evidence points to a long war and to a depletion of man power and materials which will make our present plight seem enviable by comparison. Rationing of several kinds of civilian commodities has already been put into effect, and restrictions will soon be placed on many more. There can be no doubt that a redistribution of health services will also be necessary.

The U. S. Public Health Service is now receiving a steadily increasing number of requests, under its grants-in-aid program, for financial assistance in the support of incomplete health units. A unit which has been operating under the direction of a full-time medical officer loses that officer to the military forces, and a request is made that the unit be allowed to continue without a full-time medical director. Obviously, this is not a feasible solution if a satisfactory

standard of service is to be maintained. Instead of attempting to operate in a headless manner, such a unit should pool its resources with a neighboring unit which has a medical health officer. In this way it can continue to operate under the competent direction which is necessary to produce desired results.

What I have said concerning the necessity for complete coverage of the country by full-time, professionally staffed health units may arouse some misgivings in those who advocate state administration of local health services. Considerable difference of opinion exists with regard to the relative merits of centralized vs. local direction. This, however, is not the subject I am discussing. I recognize that there are circumstances of time, place, and type of service which bring out the advantages of one plan as contrasted with the other. The point I wish to make is that, regardless of where ultimate authority lies, it is chiefly at the community level that the service must be performed. And, as I said before, by a community I do not mean a village or an artificially established political unit. Almost all sections of the country today are tributary to some population center which satisfies a majority of the inhabitants' needs. To such centers people go for education, recreation, the purchase and exchange of commodities, and, in the main, for medical treatment. They do not look to the crossroads village for satisfaction of these needs, nor do they depend upon the state capital.

It is in such recognized community centers that public health services must be established and maintained if they are to operate economically and efficiently. Whether the local health unit should have a high degree of autonomy or whether its activities should be directed by a central state authority is a matter of opinion or local tradition, and is perhaps relatively immaterial. What is important is that the health unit gear

its activities to the needs of the people, and that it provide an integrated set of services with a minimum of waste motion and expense. To do this there must be direct contact and community of interest between those who provide the service and those who benefit by it. When such conditions prevail the health unit is in a position to become a potent force in the community.

Despite an intricate mosaic of local jurisdictions, the administration of essential public health services in Pennsylvania is centralized to an unusually high degree. This system has some decided advantages. It is, for example, well adapted to overcome the Balkanization which frequently characterizes health services operated as locally autonomous units and supported principally by local taxation. This does not mean, however, that local health services can be operated successfully over a period of years by remote control through a corps of circuit riders who make occasional visits to the individual communities. Such persons have no roots in the community and cannot hope fully to understand or meet its needs. There is a tendency among health workers of this type to go into a locality more or less in the manner of traveling salesmen, each with his own stock-in-trade. In peddling their wares they often find themselves in direct competition with others from the central office who have their own stories to tell or their own lines of goods to sell.

Now that transportation has been drastically curtailed, the visits of these emissaries will necessarily be less frequent. The state health department's control will thus become even more remote, and the communities will have to depend to a greater degree upon local initiative and resources. I am sometimes inclined to believe that the curtailment of transportation resulting from the war may actually serve to enrich the content of public health programs. For some time, at least, our health circuit riders

may be forced to remain static long enough to do a thorough job in one locality before moving on to the next.

Let us assume for purposes of discussion that a community possesses a health organization capable of carrying out a satisfactory program. What then should be the content of the program? The situation at this time calls for re-emphasis upon those basic aspects of public health activity which engrossed the attention of our early health administrators—elementary sanitation and law enforcement. By this I mean the maintenance of ordinary communal cleanliness—a safe water supply, proper disposal of sewage and garbage, milk that is fit to drink and food that is fit to eat, restaurants that are conducive to appetite, absence of vermin, decent housing, and a safe and hygienic working environment. To those basic needs must be added the provision of medical care, a function which was originally a part of poor relief but which increasingly is being recognized as an essential part of a health program.

These basic activities—sanitation, law enforcement, and medical care—are today more or less taken for granted, as if they would take care of themselves. In recent years greater stress has been placed on certain less basic functions of an educational or promotional nature. These activities are not without considerable value, but there are some things which simply cannot be talked or educated away. One is filth and another is sickness. There is unmistakable evidence that simple sanitary services and general medical care—neither of which we have ever developed to a satisfactory degree—are now breaking down in many areas in the country. I believe that for the duration of the war the chief instruments in the health officers' armamentarium will once again have to be the shovel, the club, and the pill bag. A health conservation contest is not the way to approach the problems of a

population that has become lousy, nor will an educational campaign serve to remedy a water supply that is being polluted by an insanitary trailer camp. Fortunately, war and calamities in general have a way of emphasizing the elemental factors in human existence.

There are several reasons for the breakdowns which are now occurring. First, there is the dislocation of population to which I have already referred. Second, there is a scarcity of materials upon which we have come to depend for various types of sanitary devices and installations. There is likewise a growing labor shortage, and an acute lack of engineering personnel. With regard to the distribution of medical care, the situation is truly alarming in many communities. Doctors, dentists, and nurses have been withdrawn in large numbers from civilian service. At the same time, people once again have money to spend, and are seeking medical care which they could not afford prior to the war boom. Industrial hygiene and related medical service, largely neglected throughout our years of remarkable industrial development, have now taken on compelling significance because of the urgency of war production.

In addition to intensifying the need for action along traditional lines, the war has also brought to health departments some entirely new problems. Chief among these are the many-sided aspects of what is termed "civilian defense." This includes the organization of emergency medical and hospital services in preparation for possible enemy action, the establishment and maintenance of blood banks, and the protection of public water supplies against contamination or actual damage.

It is quite apparent that these increased duties—both old and new—cannot be discharged without readjustments in organization and methods. Ingenuity is demanded in many respects, but most important of all is the utilization of

available personnel to the greatest possible advantage. This involves not only rationing of services, but redistribution of skilled workers. Professional personnel must be reassigned to localities and tasks in which their services are most needed. After suitable orientation training, auxiliary personnel should be utilized for the performance of many functions heretofore discharged by persons with special professional qualifications and training. Educational and training processes by which students are prepared for employment in medical, sanitation, and allied fields must be accelerated.

In turn, if existing staffs or obtainable personnel are to be employed most effectively, reorganization of many types of facilities and services is essential. Idle equipment must be put to use, and all resources pooled so that they will be of benefit to the largest possible number of people. Time- and labor-saving procedures must be adopted. The provision of medical care, for example, must whenever necessary be organized around clinics and hospitals. Increased attention must be given to methods of financing medical care for the individual so that care will be more readily available to a larger percentage of the population.

These emergency measures, however, cannot be effected except around some administrative unit with the legal authority and the technical ability to put them into practice. The health department is unquestionably the organization best suited for the assumption of this responsibility.

It is evident that some of these measures cannot be applied effectively without introducing the element of compulsion which is daily coming to play a greater part in our lives. Moreover, since some of the problems are statewide or even nation-wide in scope, local initiative and responsibility will not always suffice. Nevertheless, even though state or federal action may be needed,

the local organization must constitute the framework within which the program is implemented. Regardless of the agency responsible for the over-all planning, and regardless of whether the personnel employed are on the local, state, or federal pay roll, operation must be channeled through existing or improvised community facilities and must be related to the communities' needs.

A declaration of the American Public Health Association, adopted by its executive board in December, 1941, states:

The effective modern health department, as now conceived and at present organized in many states, cities, and counties as a branch of civil government, comprises a medical, sanitary, and related biological and social competence which enjoys broad authority to meet a wide variety of medical and environmental emergencies. . . .

. . . the health officer and his staff must be alert to extend, and, if necessary, to modify the usually accepted health functions to meet

the multitude of exceptional situations certain to be created by the state of war and by the mobilization of all the people and their industry to support the armed forces.

This is a call for direct and vigorous action. It demands something more than reliance upon a process of evolution, which is a dignified term for the method known as "muddling through." This time, an attempt to muddle through will mean defeat.

The future pattern of health organization in this country depends largely upon how this challenge is met. If the basic system we have evolved slowly over a period of years proves adequate to the demands of the emergency, it will be retained as the foundation upon which the nation's future health services will be provided. If it fails, a reorganization, sweeping in character, appears to be inevitable.

Hypothetical Relationship of Water Supplies to Poliomyelitis*

KENNETH F. MAXCY, M.D., F.A.P.H.A.

Professor of Epidemiology, Johns Hopkins University, School of Hygiene and Public Health, Baltimore, Md.

THE hypothesis that poliomyelitis may be water-borne is not a new one. It has received consideration by various investigators ever since the infectious nature of the disease was recognized a half-century ago. Up to 1937 the concept received little support. During the past five years it has recruited many advocates. It is proposed here to review very briefly the present status of the laboratory and epidemiological evidence upon which this hypothesis rests.

Fundamental to the problem of how poliomyelitis is transmitted is knowledge of how the virus enters and leaves the body. Laboratory experiments on monkeys and chimpanzees and studies of human tissues obtained post-mortem indicate that the virus *enters* through the alimentary tract,¹ but do not resolve the question as to whether it is conveyed by air particles—droplets, droplet nuclei, or dust—or via contaminated articles, food or drink, or by both. In similar manner, laboratory studies² leave doubt as to whether nasopharyngeal secretions or intestinal discharges, or both, are of importance as a medium of *exit* for the virus in order that it may reach new hosts. Recent discussions have centered attention very largely upon the latter as a

possible route of transmission, that is, by fecal contamination.

The studies of Kramer, Gilliam, and Molner,³ of McClure and Langmuir,⁴ and of Piszczek, Shaughnessy, Zichis, and Levinson⁵ have demonstrated that the virus may be present in the stools of persons not clinically ill or with illness of ill-defined character, as well as in those of persons suffering from paralytic or recognized abortive attacks. It may be recovered only upon a single occasion or found to persist up to several weeks. There is one instance on record⁶ in which the virus was isolated from the stool of a child who had sustained a mild attack of the disease 123 days prior to the time when the test was made. It is generally agreed that the amount of virus in feces of human cases may be large, much larger than the amounts found in nasopharyngeal secretions. Paul and Trask⁷ estimate that between 1,000 and 10,000 doses infective for the monkey may be present in 50 gm. of stool. *These facts suggest that in nature human fecal material is a copious source of the virus of poliomyelitis. From this source it has been traced for short distances and limited time periods in domestic sewage.* Paul and Trask,⁸ in a large number of trials, were able to recover it in 4 instances where samples were collected in close proximity to hospitals in which patients with infantile paralysis were being treated. When samples of urban

* Presented at a Joint Session of the Laboratory, Engineering, and Epidemiology Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

sewage were collected at random after epidemics in large cities, 22 tests were negative. When samples were collected routinely over a long period of time, at intervals of about 1 month, in New Haven and in New York, 85 were negative and from 2 the virus of poliomyelitis was recovered.

The 2 positive samples came from the Manhattan Grit Chamber, located in the heart of New York City—one in September, 1940, and the other in October, 1941—at a time of year when the incidence of the disease is maximum. In neither year, however, was it regarded as being epidemic. These observations may be interpreted as suggesting that under some conditions in human sewage the virus remains stable and may survive in detectable quantities for at least a short time.

Laboratory experiments also lend support to the idea that the virus may remain viable for some time outside of the human or animal host if conditions are favorable. Suspensions of human feces kept in the refrigerator for months may be found active upon inoculation into monkeys.

Moreover, it must be granted that it is theoretically possible that this virus in polluted water might pass through a treatment process used in purification for drinking purposes which would be adequate to retain or destroy *Escherichia coli*. Bacteriological standards of safety, using the density of *Escherichia coli* as an index, and based upon experience with typhoid fever, would not necessarily apply to this problem. Whether the chlorine concentrations ordinarily realized in the treatment of drinking water or of swimming pools is sufficient to inactivate the virus of poliomyelitis is still a matter of uncertainty.^{7, 9} Many experiments designed to answer this question have been performed, but because of technical difficulties they do not lend themselves to ready interpre-

tation of practical operating conditions. The same criticism may be offered with regard to the recent claim of Carlson, Ridenour, and McKhann that purification as ordinarily employed fails to destroy or remove the virus completely.¹⁰

Granting the possibility, the fact remains that up to the present time no one has conclusively demonstrated the presence of poliomyelitis virus in water used for drinking or bathing purposes, with one possible exception. Carl Kling,¹¹ in the State Bacteriological Institute in Sweden, has for several years tested samples of water from supplies which epidemiological observations suggested might be involved in transmission. Methods have gradually been improved. It is reported that during the period from July 1, 1938, to June 30, 1939, 27 such samples were tested by animal inoculation, and one of these was regarded as positive.

This positive sample came from a well which was suspected of being the source of infection of a 6 year old boy living on the same property. It was obtained the day *after* discovery of this case. The well was in dilapidated condition with walls of rubble and obviously open to human pollution. A virus recovered by animal inoculation was classified as belonging to the poliomyelitis group, although the strain had a low virulence for monkeys (*Macacus cynomologus* and *Macacus rhesus*) and the histological changes were not altogether typical. This is a suggestive result and, so far as I am aware, the only report in the literature of a poliomyelitis-like virus recovered from water which was customarily used for drinking purposes. However, failure in this respect with the methods available does not prove the absence of virus in sufficient quantities to infect, any more than does failure to demonstrate typhoid bacilli prove the innocence of a suspected water supply as a source of typhoid cases.

In summary, the evidence and considerations from the studies which have been briefly reviewed are consistent with the hypothesis that poliomyelitis may be water-borne. But they are also consistent with the hypothesis that this mode of transmission is unimportant, even though direct transfer of fecal material from infected to non-infected individuals in close contact is the ordinary route by which the virus travels from person to person. Indeed, they are not inconsistent with the hypothesis that the virus in feces is inconsequential in transmission, and that effective exit for transfer to a new host is made by air-borne secretions of the upper respiratory tract.

That water is a medium of transmission of *biological importance* can be accepted only if it can be shown that the behavior of the disease in nature can be satisfactorily explained on this basis. It is not sufficient merely to show that the causative parasite leaves the body of the human host in feces and survives a short time in sewage. If this were the only requirement, tuberculosis might have been classified as water-borne. It is not sufficient that a group of cases of an infectious disease be traced to drinking water polluted by back-siphonage in a plumbing system. A group of students at Michigan State College were infected with *Brucella melitensis* as a result of such an accident.¹² It is not sufficient that cases occur along water courses and river valleys even if the microparasite were recovered from samples of the water. Two small epidemics of tularemia in man, one in Russia¹³ and one in Turkey,¹⁴ have been attributed to drinking from streams which were contaminated with this organism. Jellison, Kohls, Butler and Weaver¹⁵ have reported an epizootic of tularemia that affected the beaver in numerous Montana streams from the late fall of 1939 to the late spring of 1940. Water from

four streams was shown to be contaminated with *Pasteurella tularensis*. This suggested the possibility that contaminated stream water might be an occasional source of human infection, yet it does not justify classification of human tularemia as water-borne. More evidence than this is needed. *It must be convincingly shown that the behavior of a disease in human communities is such as would be expected if the causative parasitic microorganism were dependent for continued dissemination, in part, or at times, upon the medium of contaminated water.*

Specifically, what is the behavior that would justify such an inference? The question can best be answered by reviewing certain observations which have been made with regard to the prevalence of cholera and typhoid or paratyphoid fever; dysentery, or diseases generally accepted to be water-borne.

In general, their prevalence has been correlated with a poor sanitary environment including, but not necessarily depending directly upon, water supplies subject to human fecal pollution. In communities with a common water supply subject to such pollution, the incidence has tended to be excessive and cases were scattered throughout the population in time, in place, and in persons (except as modified by immunity), as would be expected from a wide dissemination of the infective agent through the water distribution system. In some instances it has been possible to show that the incidence of one of these diseases was significantly greater in the group of people using the suspected water supply than in another or other groups using a different supply but *alike in all pertinent respects*. A classical example is John Snow's analysis of the mode of communication of cholera in South London.

In other instances it has been possible to show that an abrupt decline in incidence immediately followed the in-

stallation of a water purification plant with living conditions changed in no other important respect. Or, *per contra*, increased incidence has abruptly followed some breakdown in the treatment process or distribution system of a common water supply. Numerous examples of these contingencies can be found in the typhoid history of American cities and towns.

Perhaps most convincing of all are the explosive outbreaks in which groups of people were simultaneously infected, and it was conclusively shown that the only medium of common dissemination to which all or nearly all could have been exposed was a water supply subject to human pollution. Finally, it is to be pointed out that wherever sanitation has been improved, including the improvement in water supplies, these diseases have been unable to maintain their prevalence in human populations and have tended to decrease or disappear. This is the sort of evidence upon which it has been generally accepted that they are or may be water-borne.

Turning now to the extensive literature on poliomyelitis which has accumulated since the initial observations of Wickman, *epidemiological evidence of this character is conspicuous by its absence*. The incidence of this disease has not been correlated with sanitary environment. It has never been shown that either the epidemic or the endemic incidence of poliomyelitis is significantly associated with the quality and safety of water supplies as determined by either a sanitary survey or by bacteriological analysis or by both. Assuming that filtration and chlorination are ineffective in removing the virus, then, for example, it would be expected that the incidence would have increased over a period of years in the cities which obtain their water from the Ohio River with its speedily increasing load of sewage pollution from domestic sources. On the other hand, it would be ex-

pected that small communities supplied with water, whether treated and chlorinated or not, but from watersheds or underground supplies which careful sanitary surveys have shown were protected from human fecal pollution, would have a conspicuously favorable experience with poliomyelitis, yet sharp outbreaks have occurred in such communities. When poliomyelitis has invaded large urban communities whose population is served simultaneously by a common water supply, the cases have not been scattered in time, in place, and persons in the sudden random fashion which is expected. The disease has characteristically manifested a slow radial or progressive spread from an initial focus. When poliomyelitis has occurred in rural areas, it has moved at a strikingly constant speed from place to place in a wholly unpredictable manner, but unaffected by the character of the local private water supplies. Finally, and perhaps most important of all, there is on record at present not a single instance of an explosive outbreak of this disease which has been attributed to simultaneous exposure of a group of people to a common source of water.

Nor can the absence of epidemiological evidence incriminating water as a medium of transmission be attributed to insufficient investigation. There are now in the literature a large number of studies made by competent epidemiologists of the conditions under which poliomyelitis occurs and spreads. Many of these investigators have had extensive experience in tracing water-borne epidemics of typhoid. Even if it be true that most outbreaks, or the majority of cases of any single outbreak of poliomyelitis, are subclinical in character, it seems quite improbable that important and pertinent facts with regard to the behavior of the disease would have remained concealed. There have been many occasions when the recognized paralytic cases were sufficiently numer-

ous to afford an index or a clue to what was happening.

In conclusion, although evidence derived from laboratory studies is consistent with the hypothesis that poliomyelitis may be water-borne, it is also consistent with transmission by other routes. On the other hand, this hypothesis is not satisfactory in explaining the natural behavior of this disease in human populations. Its epidemiological pattern differs significantly from that of other diseases known to be water-borne. There is at present insufficient evidence to justify the belief that water is a medium which is of any practical importance in spread.

Joint Responsibilities and Indirect Services of the Health Department in Environmental Sanitation*

J. LLOYD BARRON, C.E., F.A.P.H.A.

*Director, Division of Sanitation, Nassau County Department of Health,
Mineola, N. Y.*

ISOLATIONISM is a policy as unfortunate for health departments as it is for nations. Where the objectives are actual improvement of community health and sanitation, a progressive health department must of necessity integrate its services with those of many other agencies. It must also accept the responsibilities of coöperation so that there may be mutual applications of authority, technics, and facilities to problems common to several agencies—governmental or private.

The field in which opportunities are most numerous and varied for such coöperation and extension of services is that of environmental sanitation. Here the health department has contact with many other departments of government in the promotion and maintenance of an orderly and properly functioning society. The technics by which the community maintains its material functioning are essentially engineering. Construction, production, transportation, communication, sanitation, are basically engineering activities upon which the modern civilized community depends. Any health authority which would participate effectually in the physical functioning of the community must be able

to comprehend its engineering problems and to contribute engineering judgment and service to their solution.

It follows, as a matter of logic, that such a health authority must contain within its organization one or more competent public health engineers or have readily available the services, as necessary, of a sanitary engineering staff. Without such personnel, a health department is likely to be an ignorant or helpless bystander in vital aspects of a community's development or to contribute only superficially and sporadically to its hygiene. The community is an organic unit and the engineer is its physician.

This discussion deals with the relationships of the health department through its engineering division with other engineering and technical agencies and organizations. The background of the discussion is the writer's experience in a county department of health (Nassau County, N. Y.) serving a population of some 450,000 included in 68 municipalities. It is not to be inferred that the various aspects of the joint responsibilities and indirect services here reviewed have been fully or even partially exemplified in the writer's own department. However, in common with public health engineers elsewhere, possibilities of coöperation have appeared and have been developed more or less as local circumstances and resources would permit.

* Presented at a Joint Session of the Health Officers and Engineering Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

It is the usual experience of public health engineers to undertake—usually below the state level—their work in places where such service is long overdue and where neglect of sanitation has resulted in an accumulation of distressing conditions and bad sanitary practices. In such localities other departments of government are likely to be well entrenched and habituated to minor, and perhaps to major, impositions upon health department personnel. Local officials and the public in general usually have developed peculiar ideas about the functions and responsibilities of the health department, particularly with respect to sanitation and the extent of public health police powers. Under such circumstances, the local health authority upon acquiring engineering personnel must thereupon undertake the complex task of overcoming past negligence, giving guidance to the further sanitary development of the community, and educating the associated officials and the public to an understanding of its legitimate activities and interests in the province of sanitation.

Concerning environmental sanitation, the most important relationship of the local health department is that with the state health department and its engineering division. The state's supervision of major utilities such as water supply and sewerage is essentially an effort at remote control and is usually inadequate until, by districting or by the acquisition of public health engineers in local jurisdictions, technical service becomes available on a day to day basis rather than at intervals of months or years. This relationship between districts, county, and city engineers and the state engineering division should be founded on mutual confidence and interdependence. Assuming that reasonably sound engineering judgment is being used, each should give positive and consistent support to the other in decisions, programs, and projects. The

curse of political interference in engineering matters can best be resisted by a strong professional liaison between the state and local engineers. Moral stamina is required at both ends of the line to checkmate expediency and fence-straddling.

With the concentration of tax moneys in the state and federal governments and the paternalistic return of such funds for the support of local government functions such as public health work, a new phase of joint responsibility and of indirect service has developed, at least potentially. The principle of this relationship is that the contributing agency, clothed in the mantle of omniscience, imposes higher standards of personnel and performance upon the local department as a condition of the aid. The enforcement of such standards would indeed constitute the highest type of indirect service to a community, but too often the fear of offense to powerful political groups or to entrenched professional organizations permits flagrant misappropriation and waste of these funds. Statesmanship and courage of the highest order are needed to prevent the employment of incompetents and to oust those who hold sinecures. Progress in public health administration and service is cheap where it costs only the enmity of the greedy and the irresponsible.

In the fields of water supply and sewage disposal, organizations of administrative and operating personnel are quite important and have been strongly fostered by state sanitary engineers. Local public health engineers can contribute much to the functioning of these associations by bringing isolated local officials into contact with their professional groups and with each other. In Nassau County, the officials of 42 public water systems were found to have no organized relationship and little acquaintance with each other. In initiating a public health engineering program af-

fecting these supplies, the engineers of the health department found the lack of such an organization of water superintendents a serious handicap to the quick and effective dissemination of information and in enlisting general understanding and support of the work. Consequently, the health department took the initiative in forming such a group and has since furnished the clerical service and sustained its continuity. This activity has brought the water supply officials into close and sympathetic relationship with the health department, a situation contrasting sharply with their previous indifference to local health officers and remoteness from the state sanitary engineering division. Currently, this organization of water superintendents has proved to be extremely valuable in carrying out measures of wartime preparedness for civilian defense and, more particularly, the New York State mutual aid plan for water supply service, sponsored by the State Health Department.¹

Neighboring health departments have many opportunities to reinforce each other's dealings with problems of sanitation. While the state is usually the coordinating agency where waters are used jointly for public supply or waste disposal, there are many situations in which direct relationships promote quicker solutions of problems and a beneficial exchange of information and coordination of efforts. This is possible, however, only where each department has technical personnel speaking the common language of engineering and sanitation. The writer recalls his early efforts in the metropolitan area to establish helpful contacts with the New York City Department of Health. It was a disappointing experience because that department, the largest in the world in point of personnel, then had not one public health engineer on its staff, and its sanitary program was unorganized and shaped largely by the force of ex-

ternal events. Fortunately that situation was changed with the appointment of a capable public health engineer as Deputy Commissioner of the Health Department.

Since that event, satisfactory common approaches have been made to many joint problems in the metropolitan area. The establishment of local standards for bathing beaches is an example in which, under engineering direction, basic information regarding the intensity of pollution in tidal waters was obtained by systematic sampling. Ratings of beaches were then established in the several health jurisdictions, taking into account the proximity and volume of pollution sources and the recreational necessities of tributary populations. Through press releases the public was given reliable information from authoritative agencies, thereby relieving several newspapers of the occasion for well meant but actually presumptuous reports on bathing waters based on inadequate sampling and reportorial interpretations.

Responsibility for jointly used milk supplies furnishes opportunities either for conflict or coöperation among local health departments. The feeling on the part of one department that another does not have professionally competent and responsible personnel for the maintenance of a milk sanitation program is perhaps the most common obstacle to a sharing of the job. This, if true, is certainly a valid reason for distrust for which, however, the remedy is obvious. In the metropolitan area, as experienced public health engineers and technical personnel have been placed in charge of milk sanitation, an increasing degree of uniformity of regulations has been achieved, accompanied by a more confident acceptance by one department of another's work.

Present-day food sanitation concerns perhaps more agencies than any other problem in public health. The widespread sources of food supplies, their complex processing and transportation,

and the vast amount of food sold and consumed outside the home involve the local health department in a labyrinth of relationships with other regulatory bodies. The division of responsibility is usually not clearly defined and the overlapping of authority is confusing but, as these agencies slowly evolve better regulations and enforcement procedures, the integration of food control is improving.

Perhaps the most difficult relationship is that between local health and state food authorities. While the background and extent of authority exercised differ considerably in the various states, there is usually a conflict of some degree between the public health and the agricultural or marketing points of view. The state food control agency must of necessity concern itself with food quality, misbranding, adulteration, and other fraudulent practices and should properly direct its major efforts at those points where foods are handled or processed in bulk. Its local inspection should be chiefly a check on the observance of required standards and practices. This state agency must also deal with sanitation but chiefly from the standpoint of contamination, living or inert, being an aspect of adulteration. However, no practical degree of state inspection can furnish the local protection and control necessary to maintain decent standards of sanitation, particularly in the great numbers of retail establishments.

Unless the local health department recognizes rather broad responsibilities in the maintenance of food quality, it may leave a critical gap in the service properly demanded by the public. Food buyers consider cleanliness and wholesomeness of foods to be legitimate concerns of the health department, even though many such aspects of food sanitation have no obvious statistical relationship to communicable disease. The local health department can afford to ignore adulteration and misbranding of

foods only if the state agency is functioning effectively, in which case the local responsibility becomes one of co-operation with the state inspection service in uncovering and reporting violations and in itself doing well the major job of sanitary control of foods and food selling places.

The production and distribution of shellfish afford opportunities in the maritime states for coöperation of seaboard health departments with the state agency having supervision of this food. In New York State, the Conservation Department, charged with this responsibility, does not have police power for the control of pollution which may ordinarily be exercised by health departments. Consequently, in recent years this agency has had to close more and more shellfish growing areas because of increasing pollution without being able to deal constructively with the problem by abating such pollution. The establishment of a county health department in Nassau County made possible a reversal of this destructive trend. Public health authority coupled with engineering service has accomplished the abatement of hundreds of discharges of sewage and the forestalling of many more along extensive shore lines.

The U. S. Food and Drug Administration, in its enforcement of the new federal food, drug and cosmetics act has displayed a welcome desire to establish mutually beneficial relationships with local health departments. Through its division of state coöperation, this agency has extended its coverage of the country and enlisted the aid of qualified local food inspection personnel by giving them definite individual authorization to act as its agents in certain respects. These local representatives may also give vital assistance through their ability to use public health police powers for the prompt embargo or seizure of foods under circumstances in which the federal agents may be handicapped by the slower

and more devious procedures of the act.

Another federal agency with which the local health department may cooperate to advantage is the Federal Housing Administration. Residential water supply and sewage disposal are always critical problems in unsewered areas, to which the general specifications of the FHA may not apply without local modification. In Nassau County, the FHA was found to be depending upon local health officers for certificates of approval of private sewage disposal installations where the local health authority had no standards, no basis of judgment, and no uniformity. Upon the establishment of the county department of health, this relationship and service was seized upon as a means of clearing up private sewage practices. Engineering standards for design and construction, adapted to the conditions on Long Island, were prepared and were then accepted by FHA. Some 6,000 certificates have since been issued. Without having to place all private sewage disposal construction on a permit basis, the health department has thus taken advantage of the FHA plan to force numerous developers, builders, and sewage disposal contractors into proper practices, and has thereby rendered a valuable service to FHA, and to numerous purchasers of homes.

With respect to the housing problem, the local health department has many opportunities for indirect service through coöperation with other agencies concerned with slum clearance. First of all the health authority must make clear the limits of its special powers, the involvement of other departments, and the necessity of the community exercising its general police powers. The essence of housing improvement is the provision of new low rental housing, and it is only in conjunction with such a program that the health department can grapple very extensively with rehabilitation and strict enforcement of sanitary regulations.

In New York State, the legislature

has empowered municipalities to establish housing authorities which may acquire land, raze slum buildings, and construct and operate housing projects. It is with such an agency that the local health department can collaborate to best advantage in giving survey information and guidance, and in enforcing sanitary regulations contributing directly to the housing improvement. This may involve furnishing personnel and carrying through prosecutions which would be difficult for a housing authority to handle.

When the health department, such as in a county, has jurisdiction in a number of municipalities, there may be opportunity for coördinating housing activities and for stimulating parallel attacks upon bad conditions in adjacent areas which would minimize the shifting of population from the unimproved to the improved area. In the writer's experience, the local housing authorities are sometimes appointed for the purpose of conducting delaying actions rather than for a genuine attack upon the local slum conditions. In such a situation the health department must beware that it does not lend itself to an attempt to drive out of a particular community an undesired element of the population through the destruction of outworn dwellings on any considerable scale and without replacement.

In connection with housing there exists between the health and welfare departments a joint concern for the living quarters of families on relief. Welfare authorities are continually plagued with the problem of finding accommodations for tenants whom many landlords consider undesirable. Such families, with or without the guidance of welfare supervisors, may move into unsuitable dwellings, the occupancy of which may thereupon create unsanitary conditions and violations of the public health regulations. The necessity of the health department's prosecuting a landlord or

evicting a tenant to abate a violation where rents are being paid from public funds could be largely obviated by an arrangement whereby the health department would make prior inspections of housing before occupancy and indicate to the welfare officials whether or not sanitary facilities are adequate and the structures suitable. There is similar need for a satisfactory relationship between the health department and the local agency handling properties held for tax sales and also with the Home Owners Loan Corporation, the latter being the most frequently encountered owner of properties in distress. Since the health department cannot readily bring its police power to bear upon another agency of government, prompt abatement of sanitary violations depends upon that mutual respect and coöperation which should exist among responsible government officials.

Housing, in its larger aspects, becomes community planning, the newest function of municipal government. The actual application of planning as an expression of a broad and sweeping public interest looking far into the future must necessarily trample upon many private interests. The deliberate, long range shaping of urban growth requires the merging and adjustment of many diverse interests among which public health and sanitation must be included. The health department has or should have a minimum of political inhibitions and its contribution to planning should be freer and bolder than that of some other interests normally making up the planning group. The engineer of the health department, whose job it is to think more or less continuously about the environment in terms of evolving comfort and cleanliness should, therefore, be a member of such a board or of an authoritative advisory group.

Another variety of sanitary problems is encountered in our factories and mercantile establishments where basic sani-

tation and industrial hazards both require attention. In New York State, industrial hygiene is divorced from public health at the state level and local health departments find it difficult to contribute to industrial sanitation without the appearance of intrusion upon another department's responsibilities. However, where such responsibilities are not being effectively discharged and where inspection is perfunctorily performed by non-technical personnel, there seems to be occasion for local health departments having engineering personnel to deal with factory sanitation and industrial hygiene under the public health police power. Again the lack of technical personnel in the local health department or in the state agency concerned with industrial hygiene is a barrier to effective coöperation on a common problem. Furthermore, coöperation with health departments involves the risk of making clearer the fact that industrial hygiene is a function more properly in the field of public health than of labor.

Another local agency having important influence upon the environment is the building department and its related zoning board. Their dealings with many structures and uses such as factories, apartment dwellings, nursing and boarding homes, food selling places and places of public assembly, and so-called offensive trades, affect interest of the health department, and there are always the common concerns with water supply, plumbing, sewage disposal, lighting, ventilation, and prevention of nuisances. The zoning and building authority can give and derive much assistance from the health department, provided the latter has the technical personnel to express the public health view of these matters.

The regulation of plumbing, which is properly a function of the building department, is one which benefits from a positive health department interest.

However, too often the preparation of a plumbing code and the indirect control of its enforcement is turned over to local plumbers, thereby placing the public interest, the only valid basis for such exercise of police power, at the mercy of a private interest, usually both selfish and unenlightened. The influence of an official public health engineer in the community can do much in bringing about a representation of the public interest, in modernizing the regulations with respect to private sewage disposal, cross-connections, back-siphonage protection, etc.

Currently the war effort has placed new or greatly expanded military establishments within many health jurisdictions and has thereby afforded opportunities for health department personnel to render valuable but not always appreciated assistance. A rapidly expanding military post creates problems of sanitation which may not be dealt with as rationally as observant local officials would like. The sudden authority which comes to military personnel not fully prepared for such responsibilities frequently results in arbitrary action based on personal prejudices. The assumption in the army organization that veterinarians are inherently qualified to assume responsibility for milk sanitation, meat inspection and food control, that physicians are epidemiologists and that engineer officers can cope with all sanitary problems, is too frequently disproved. The writer has observed the rapid expansion

of a regular army post in the course of which county health department personnel have had opportunities to assist army authorities in matters of water supply, sewage disposal, garbage and refuse disposal, food and milk sanitation, water main disinfection, and epidemiological investigations, in addition to the usual work of the health authority in the surrounding areas.

In concluding this review, its minor theme, which has no doubt become apparent, might be more explicitly stated as—the usefulness of the public health engineer in representing and extending the influence of the local health department. It is an invitation to the local health officer, now without such administrative and technical assistance, to consider the manifold ways in which his authority and service to the community may be expanded and strengthened. The activities here reviewed are so essential in the functioning of the larger municipal and county health jurisdictions that the local health officer, in failing to provide both the direct and indirect services of the public health engineer, is, in effect, inviting other agencies of government to meet the need. The local health department cannot afford to default on environmental sanitation if it is to assume its proper responsibilities in the service of the community.

Tetanus Toxoid, Its Use in the United States Army*

MAJOR ARTHUR P. LONG, M.C.

United States Army, Division of Preventive Medicine, Office of the Surgeon General, Washington, D. C.

IN 1924, Descomby¹ produced tetanus toxoid by the application of the technic Ramon² had described for the removal of the toxic properties from diphtheria toxin. Later, Ramon and Zoeller,³ having demonstrated its antigenic value, suggested the use of tetanus toxoid as an agent for active immunization against tetanus. Since that time, the value of this procedure has been demonstrated by many workers, and active immunization with tetanus toxoid has largely supplanted passive protection with antitoxin for the prevention of tetanus among battle casualties. Reports from the British and French Armies have indicated its efficacy under actual battle conditions, as has the experience of our own troops in combat zones.

THE PRESENT PROGRAM

Plans for the active immunization against tetanus of American troops were made early in 1940, and in the fore part of 1941 the procedure was adopted as routine for all military personnel on active duty.

The agent selected was fluid or plain tetanus toxoid. The toxoids used by the U. S. Army are procured from commercial biological laboratories licensed

by the National Institute of Health for the production and sale of this material. The toxins which are converted into toxoids are produced in infusion broth media fortified by various types of peptones or meat digests. These toxoids must conform in all respects to the requirements of the Biologics Control Division of the National Institute. To meet these requirements, the original toxin must have a potency of at least 10,000 guinea pig m.l.d. per ml., and be detoxified by the addition of not more than 0.4 per cent of formalin. The toxoid so produced must be shown to be completely atoxic for guinea pigs when injected subcutaneously in doses of 5 ml. The retention of specific antigenicity is demonstrated by the subcutaneous injection of 1 ml. of the toxoid into each of a group of guinea pigs. At least 80 per cent of the animals so prepared must show complete protection against 10 m.l.d. of toxin administered 6 weeks later. In addition to these and the other requirements of the National Institute of Health, the toxoid used by the Army is subjected to certain additional safety tests prior to its distribution.

The decision to employ fluid rather than alum-precipitated toxoid was not entirely an arbitrary one. This decision was based in large part on the satisfactory experience of the British and French with the use of a fluid prepara-

* Presented before a Joint Session of the Health Officers, Laboratory, and Epidemiology Sections of the American Public Health Association at the Seventy-First Annual Meeting in St. Louis, Mo., October 27, 1942.

tion. The relative infrequency of reactions attending the administration of this form of toxoid and the evidence at hand attesting to its efficacy were thought to constitute a sound basis for its adoption.

In the consideration of the use of alum-precipitated toxoid, its antigenic properties were well appreciated. However, the use of such precipitates had been limited for the most part to the administration of alum diphtheria toxoid to children. This lack of experience with precipitated toxoids in adults, and the knowledge that the addition of alum to an antigen in many instances tends to increase its sensitizing action, were additional factors influencing the choice of the type of toxoid.

The use of toxoid for the development of adequate protection against tetanus involves the establishment of a basic active immunity and the subsequent reinforcement of this immunity by the administration of stimulating, or booster, doses. Such a procedure is currently followed in the Army.

As soon as possible after entrance upon active duty, all military personnel are given a series of three subcutaneous injections of tetanus toxoid. The doses are 1 ml. each and are administered at intervals of 3 weeks. Under ordinary circumstances, a single stimulating dose of 1 ml. of the toxoid is administered at the end of one year after the initial series. As an added safeguard, a single stimulating dose of 1 ml. is administered during the month prior to departure for a theater of operations, unless such departure is within the 6 months period subsequent to the administration of a previous dose. The completion of the initial series and the administration of the first stimulating dose are recorded on the individual's metal identification tag, as well as in his personal immunization record.

An emergency stimulating dose of toxoid is administered upon the incur-

rence of wounds or severe burns on the battlefield, at the time of secondary operations or manipulations of old wounds, or at any other time when danger from tetanus is considered to be a possibility. Antitoxin is not administered for prophylaxis unless there is reason to doubt that the individual in question had previously received at least the initial series of toxoid injections. If such a doubt does exist, a prophylactic dose of tetanus antitoxin is administered and active immunization with toxoid is initiated at the same time.

REACTIONS

While the administration of tetanus toxoid has been attended by some reactions, particularly early in the program, these have not constituted a major problem and have not seriously hampered the practice of active immunization.

The reactions encountered may be classified into two main categories. Those in the first category have caused no concern and are manifested by such symptoms as headache, weakness, general malaise, local soreness of the arm, and occasionally chills and fever. Such reactions are not unlike those occurring following typhoid vaccination. However, these reactions apparently occur with less frequency after the administration of tetanus toxoid than following the injection of triple typhoid vaccine.

The second category of reactions is made up of those occurring, in the majority of instances, within 30 minutes after the injection. They are characterized in general by flushing and itching of the skin, local and generalized urticarial eruptions, and edema of the lips and eyelids. Occasional instances of edema of the glottis and dyspnea have been observed. These reactions, like those described above, have not been encountered with any great frequency. The reported incidence during the early part of the immunization program was about 0.05 per cent of injections, or

about one such reaction in every 2,000 injections. This incidence has now decreased markedly, for reasons which will be brought out later.

The nature of these reactions, rather than their frequency, stimulated considerable interest in them and their cause. It became apparent very soon that they were manifestations of sensitivity to some constituent of the toxoids being used. This was confirmed in several instances by the exhibition of typical skin reactions of sensitivity to the intradermal injection of 0.1 ml. of a 1:100 dilution of the toxoid which had been administered just prior to the reaction. At the same time, several individuals, who had exhibited reactions not attributed to sensitivity, responded negatively to similar tests. Approximately 85 per cent of the reactions of sensitivity occurred after the second or third injection, indicating that at least a portion of the reactors had been sensitized by a previous dose of toxoid.

In view of the observations of Whittingham,⁴ Parish and Oakley,⁵ and Cooke and his associates,⁶ the reports of reactions were analyzed to determine whether or not there seemed to be any connection between the number of reactions reported and the type of peptone contained in the toxoid. This analysis indicated that those toxoids containing Witte or Berna peptones were responsible for the large majority of the reactions. From data collected early in the program, it appeared that the proportion of reactions of sensitivity following the injection of these toxoids was at least six times that following the use of toxoids free from these particular peptones.

As a result of these findings, the procurement and distribution of tetanus toxoid containing Witte or Berna peptones were discontinued. As indicated above, the incidence of reactions of sensitivity has fallen sharply since that time. The exact proportion of such re-

actions following the administration of the currently distributed toxoid is not known. At the present time, reports of such reactions are extremely rare and the reporting of the total number of injections administered tends to be incomplete in the absence of reactions. It is considered to be a reasonable estimate, however, that the frequency of these reactions is now less than one in 10,000 injections.

While this incidence is extremely low and gives rise to no real concern, it must be borne in mind that the toxoids in current use do contain certain peptones and other proteins which may be potential sensitizing agents. These toxoids do give rise to occasional primary reactions and have been shown to be capable of producing positive skin tests in individuals who have previously reacted in a sensitive manner to Witte and Berna peptone toxoids.

Shortly after the appearance of the reactions of sensitivity, it was suggested that tetanus toxoid produced on a simplified medium such as that reported in 1940 by Mueller and Miller⁷ might be utilized. Mueller⁸ has carried on intensive investigations along this line since that time, and has produced tetanus toxoid in his own laboratory, using a casein hydrolysate medium. Some of this toxoid has been used as skin test material in individuals known to be sensitive to Witte and Berna peptone toxoids. There were no positive reactions elicited, although, as indicated above, many of these same individuals did react positively to certain of the toxoids in current use. Some of the commercial laboratories have also worked on this problem, but they have not, as yet, made available satisfactory toxoids produced on the simplified medium. It is understood that these investigations are continuing, and it is hoped that toxoids produced in protein-free media or similar non-reaction producing media, can be made available.

RESULTS

Within the experience to the present time, the results following the use of toxoid in the manner described have been completely satisfactory. While no large-scale studies for the determination of blood antitoxin levels have been made, the antitoxin content of several small groups of blood sera has been determined.* One group was studied in relation to the length of time required to develop protection after the completion of the initial series of injections. Serum specimens were obtained from each of 9 individuals 1 week after the last injection of the initial series. At the same time, a fourth, or stimulating, dose of toxoid was administered in the same manner as if required by a potentially infected wound. A week after this fourth injection, additional serum specimens were obtained. All of the first specimens taken (1 week after the third dose) contained at least 0.1 unit of antitoxin per ml. and three contained 1.0 unit or more per ml. Of the sera taken 1 week after the fourth, or stimulating dose, two contained more than 0.1 unit, but less than 0.5 unit; three contained more than 0.5 unit, but less than 1.0 unit; and the remainder contained at least 2.0 units of antitoxin per ml. Since the amounts of circulating antitoxin necessary for protection have been stated by various workers to be 0.01 unit to 0.2 unit per ml. of serum,^{9, 10} it was considered reasonable to assume that there is adequate protection, based on active immunity, after the completion of the initial series of three injections of tetanus toxoid and that there is no indication for the use of prophylactic antitoxin after this immunity has been established. In this

respect, it would appear obvious that circulating antitoxin resulting from active immunization is potentially more significant immunologically than is that obtained as a result of passive immunization.

Serum specimens have also been obtained from individuals just before and 1 week after the administration of the stimulating dose given 1 year following the initial series. Sera collected in this manner have been found to contain 0.001 to 0.1 unit of antitoxin per ml. before the stimulating dose, and, in the majority of instances, more than 0.6 unit per ml.† 1 week after the stimulating dose. These titers correspond closely with those obtained under more or less similar circumstances by Sneath and Kerslake,¹¹ Lincoln and Greenwald,¹² Gold,¹³ and others.

Under ordinary conditions, the incidence of tetanus in the Army, as in the civil population of this country, is very low. Since June, 1941, when the present tetanus immunization program was adopted, there have been but 4 cases reported from the entire Army. None of these were in immunized individuals. It is of especial interest to note that no cases of tetanus have been reported from battle casualties. This may assume some significance when considered with the fact that other anaerobic infections have been reported from certain of the active theaters and that, in one of these areas at least, considerable potential danger from tetanus infection is known to exist.¹⁴

It is perhaps too early in the experience of the present war to draw any conclusions from the evidence at hand. However, it is believed that the present practice with respect to the prevention of tetanus among battle casualties affords our fighting forces a maximum of protection.

* The antitoxin determinations reported were performed by Benjamin T. Sockrider, at the National Institute of Health, Bethesda, Md., and the serum specimens were collected by various medical corps officers at the Army Medical School, the Washington General Dispensary, and elsewhere.

† The actual antitoxin content of many of these sera was not determined, since, in most instances, they were not tested for more than 0.6 unit per ml.

Surveys of the Nutrition of Populations*

Description of the Population, General Methods and Procedures,
and the Findings in Respect to the Energy Principle (Calories)
in a Rural Population in Middle Tennessee

PART 2

JOHN B. YOUMANS, E. WHITE PATTON, AND RUTH KERN

*Department of Medicine and the Department of Biochemistry, Vanderbilt
University, Nashville, Tenn.*

RESULTS

The mean calorie intakes according to age, sex, and race, together with related factors, are shown in Table 6 where they are compared with the recommended daily allowances of the Food and Nutrition Board of the National Research Council.† The age groups have been selected to correspond to those used in the recommendations. Subjects under

one year of age have been omitted from this and subsequent tables because many were breast fed, at least in part, and we were unsuccessful in determining accurately the calorie intake. Furthermore, the great variation in requirements month by month in this age period would necessitate separation at many points. With only about 2 per cent of subjects (25 individuals) in this entire

‡ Baldwin-Wood Tables

* The studies referred to herein were conducted under the auspices of the International Health Division of the Rockefeller Foundation of New York City by the Nutrition Unit of the Departments of Medicine and Biochemistry of the Vanderbilt University School of Medicine, Nashville, Tenn.

† Only the individual, three day record of intake has been utilized in this analysis. An analysis of the food intake as revealed by the week's inventory and purchase and a comparison of the latter with the individual intake records will be the subject of a later paper.

group the sub-groups would be so small that the data would have no statistical significance.

It will be observed that with the exception of the 1 through 6 year white subjects the mean calorie intakes in every instance were significantly less than the daily allowances of the Food and Nutrition Board. This deficit increases irregularly with increasing age

and is greater in the Negroes. The deficit ranges from 274 calories in the case of the 7-9 year male and female whites to a maximum of 1,735 calories in the 16-20 Negro males.

The distribution of the calorie intakes for race, age, and sex is shown in Table 7 together with the standard deviation and the standard error of the mean. If 1,250 calories be taken as the mini-

† M = Male; F = Female

imum recommended intake for all ages over 1 year (the lowest recommended allowance of the Food and Nutrition Board for subjects over one year of age is 1,200 calories) 14.3 per cent of white subjects and 42.1 per cent of colored subjects, or 23.4 per cent of all subjects one year or older had intakes below the minimum. As might be expected, the highest incidence of failure to meet the recommended allowances, 75.6 per cent, was in the youngest group, (1-3 years), those whose recommended allowance is practically at the minimum level for the entire group. However, the second highest incidence, 29.1 per cent, is in the females 21 years and over. Divided into white and colored the figures are 61 and 93.9 and 18.6 and 54.9 per cent respectively. Because the table does not indicate the levels of intake below 1,000 it is impossible to determine completely the magnitude of the apparent deficit in the age group 1-3.

calculated from the recommended daily allowances of the Food and Nutrition Board. In many of the groups the ratios calculated from our data are quite similar to those calculated from the recommended allowances indicating that for those groups the proportionate distribution of food as concerns calories was usual though at a lower absolute level, compared with the recommended allowances. However, for certain groups a considerably lower ratio is found. These include males and females of 10-15, both sexes of the colored 16-20 year olds, and the white males of this same age group, as well as the females of 21+ of both races. In addition the Negro children 1-3 have a lower ratio. The tendency for the lower ratios to be most frequent in the age groups around puberty indicates a significant lack of correspondence between intake and the large allowances suggested for this period.

comparison. In Tables 10 and 11 the same data are given for fat and for total protein.

The distribution of the various nutritive principles with respect to all of these factors is distinctly abnormal in certain age groups, and there the standard deviations may not have their usual significance. For this reason the actual distributions are given, and in Table 12 the quartile distribution is also given.

The only practical objective evidence

of the adequacy or deficiency of calories is the body weight which can be measured or can be estimated on the physical examination. The latter is based largely on an estimation of the amount of subcutaneous tissue in relation to the size, age, sex, and constitution of the individual. This can be supported by a statement regarding a tendency to overweight or underweight and a history of recent loss or gain in weight from the medical history. None of the latter two

procedures are usually considered reliable in the assessment of nutrition. They are gross measures of nutrition in respect to calories, and although valuable in clinical practice are not generally considered reliable in the mass study of nutrition. We have included them, however, because the history of weight and changes in weight support other measures of energy nutrition and because the estimate of the subcutaneous tissue is the only objective measure of this same factor other than the weight of the subject, and, in children, certain other anthropometric measurements.

The lack of helpfulness of the history is shown by the results. Only 4 subjects gave a history of a tendency to obesity (1 colored adult female and 3 white adult females), and only 4 a history of a tendency to underweight (1 white male, 2 female adults and 1 colored girl in the age group 16-20). This despite the disclosure by examination and body weights of much obesity and underweight which had obviously existed a considerable time. Similarly only 8 subjects gave a history of abnormal recent loss of weight (3 white male adults, 1 white female adult, 1 colored man, and 3 colored women). *Only 1 colored subject* (female 16-20) gave a history of an abnormal increase. One white child (7-9), one white male (16-20), and a white woman reported an increase.

The estimate of the amount of subcu-

taneous tissue, however, proved surprisingly accurate in the cases in which a decrease was diagnosed. This diagnosis was made in about 10 per cent of the subjects. An abnormal decrease in subcutaneous tissue was noted in 99 of the subjects, and comparison of the actual recorded weights with the standard predicted weight for age, sex, and height showed a significant underweight in all but 5. Thus, the clinician's estimate of underweight was accurate in 95 of the 99 in which he made that diagnosis. However, many other subjects who were under their predicted weight were not so diagnosed by the examiner.

Analysis of the estimates of overweight and underweight from the amount of subcutaneous tissue (Table 13) shows that the findings conform in general to the abnormalities in mean weight shown in Table 6. In Table 13 what appears to be a significant sex difference should be noted. Of the 36 white males aged 13 or over, only 15 were adjudged overweight while 21 were thought to be underweight. Of the 86 white women of the same ages, 57 were judged overweight and only 29 underweight. The difference is even more striking in the Negroes. Five males were overweight and 8 underweight, while 33 females were overweight and only 6 underweight.

The weights of the subjects, which are the best objective measure of nutrition in respect to energy, are shown in

Tables 6 and 14. In Table 6 the observed mean weight is compared with the predicted weight for mean height and mean age of the various age, sex, and race groups. Table 14 gives the distribution according to age, sex, and race with the highest and lowest observed weights, mean and median weights in each group, and the standard deviations. As can be seen in Table 6, in 8 of the 20 groups the observed mean weight was significantly less than the predicted, the deficit ranging from 5 lb. in the 7-9 and 10-12 colored children, to 14 in the 13-15 white females. The children, white and colored, from 1-6 years of age, the women both white and colored 21 years and over, and colored males and females 16-20 had mean weights equal to or greater than the predicted.

Still one other method for detecting an inadequate calorie intake remains, the x-ray examination of the skeletal system of children for evidence of delay in growth and maturation. These changes are not specific; delay or arrest in growth and maturation occur with other nutritional deficiencies, perhaps even more strikingly, as well as with other disease. Hence, such evidence is of value in a negative way only; if no

interference with growth and maturation is found it is unlikely that nutritional deficiency, even a deficiency of calories of a significant degree, is present.

However, such abnormalities are measures of current nutrition only in earlier childhood when the developmental changes are sufficiently rapid to reflect current nutrition. Results of the x-ray will be reported later in analysis of all factors affecting the bones. Preliminary examination of the data shows little or no evidence of a deficiency of calories detected by this means.

Due to the extreme variability in the calorie requirements and the predicted weight of children less than one year of age, the data on this group are presented individually in Table 15. This group is composed of 11 white and 14 colored children ranging in age from 2 days through 11 months.

In the white group, 7 of the 11 children were partially or completely breast-fed. Since we were unable to quantitate this food, it is impossible to compare their calorie intakes with their needs. Only one child in this breast-fed group deviated strikingly from the predicted weight. This child was 4 lb. underweight in spite of the fact that, in addition to breast feedings, her accessory

† From table prepared by R. M. Woodbury for American Child Health Association.

feedings exceeded the calorie needs. Two individuals were not breast-fed, and both were receiving slightly less than their predicted calorie requirements (65 and 87 calorie deficit). One was found to be 6 lb. below the predicted weight and the other only 1 lb. below. The status of the 2 remaining white children is indefinite due to inadequate data.

Ten of the 14 colored children were known to be breast-fed. Of this group only one differed significantly from the predicted weight and was 4 lb. under this weight. Two children received no breast feedings. One received only 694 calories as compared to a predicted need of 900 calories. This individual was found to be 4 lb. underweight. The height and weight were not obtained on the other child who was not breast-fed. The complete dietary data on the re-

maining 2 colored children were not complete, but both were within 1 lb. of their predicted weight.

DISCUSSION

The data presented above seem to indicate a serious deficiency of calories (energy) in the diet of a large number of the population under study and the existence of a state of undernutrition in respect to this factor as disclosed by the body weight and the physical examination. All groups of the population except white children from 1 to 6 years of age were found by our records to have had a calorie intake significantly and often greatly below the recommended allowances of the Food and Nutrition Board. In certain groups the deficiency was as great as 45 per cent; only a little over half of the recommended number of calories daily were

consumed. These findings are supported by the existence of a significant degree of deficiency in the mean weights for many of the various groups of subjects and the finding of a considerable number of subjects with an abnormally small amount of subcutaneous tissue.

However, there are certain objections to a conclusion that there existed an undernutrition of this kind as frequent and as severe as appears from the data. In the first place, not all the groups had a less than predicted mean weight. Eight of the 20 groups had a mean weight equal to or greater than the predicted. Four of those groups were children, white and colored, 1-3 and 4-6. The others were colored males and females 16-20 and adult females of both races. Thus of these 8 groups, 5 were colored, the subjects who had the greatest apparent deficit of calories. Not only were the mean weights equal to predicted, but a very considerable number of the subjects were recorded as obese. Very few indeed reported losing weight or being underweight. Furthermore, it should be observed that the recorded calorie intakes in many instances are not only relatively but absolutely so low that their continuance for any but the shortest periods would seem inevitably to be followed by disabling loss of weight and strength. Many intakes are no greater than the content of reduction diets whose caloric value is calculated to be less than the basal requirements for "ideal" weight. Theoretically, on such diets the body weight should fall and the degree of activity be reduced until they reached levels which could be maintained by the energy supplied. On such diets as many of those indicated here, a disabling loss of weight and strength with a greatly limited activity would be expected. Yet, few if any of these subjects showed such symptoms, and many were not only of normal weight but were actually obese.

There are several possible explana-

tions for this apparent inconsistency. The food intake records may be inaccurate. The standards or accepted requirements with which the actual intakes are compared may be too high. The subjects may have been so inactive as to need little more than basal requirements. None of these explanations alone seems adequate though a combination of them may be. The records of food intake admittedly have a large margin of error. However, energy is one of the nutritive factors more easy to measure and calculate accurately. The calorie values of food have been well studied and quite accurately determined. Foods high in calories are in general easy to measure and record. It is likely that in a study of this size errors occur in both directions, over and under, and tend to cancel out. Furthermore, it is unlikely that they would consistently be large enough to explain the discrepancies found. Even an error of 20 per cent in one direction would still leave many subjects gravely inadequate in the intake of calories.

It is admitted that the recommended allowances are not intended to indicate the minimum but are those which are believed adequate and necessary for good nutrition on practical diets. Many other standards of requirements have been proposed, some of which call for somewhat smaller allowances of the various factors. The standards of the Food and Nutrition Board of the National Research Council have been based on the most recent evidence. In view of the inability to determine the actual minima under all circumstances, they might be taken as a reasonable standard, a divergence from the standard being interpreted in a relative and quantitative fashion. Yet, in view of the evidence disclosed in this study, it may be questioned whether the recommended allowances have not been placed too high. In this connection it is of interest to note that the over-all average intake

of calories in Milam's⁶ survey in North Carolina was 2,000 calories. Also, recent careful studies of the intake of a few individuals^{6,7} have disclosed intakes considerably below the usually recommended allowances unaccompanied by body weight below the calculated ideal and even associated with weights above that level. For instance, a normal man of 48, of more than moderate activity, was found to consume a daily diet of some 2,000 calories (in contrast to a recommended allowance of 3,000 calo-

ries). Yet, on this apparently low intake he had trouble avoiding an increase in his weight which was almost exactly at the calculated ideal.

Because of the discrepancy between recorded calorie intakes, recommended allowances and body weight, the relation between basal requirements, recorded intakes (calories), and the body weight in relation to predicted "ideal" weight, was investigated in a representative 10 per cent sample selected at random. This revealed that as many as a third

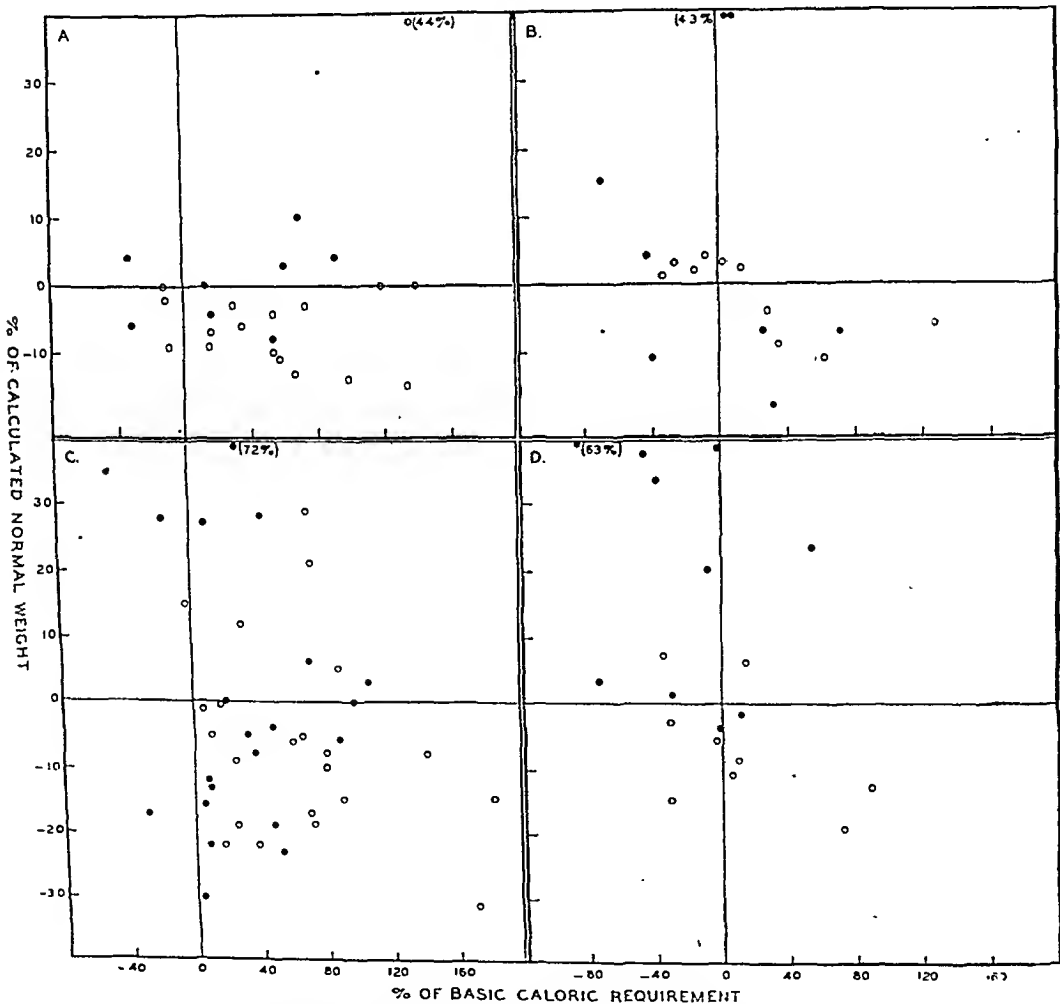

FIGURE 1—Graph showing the relation between calorie intake and weight of a representative sample selected at random (10 per cent). The horizontal axis represents calorie intake in per cent of basal requirements, the vertical axis the body weight in per cent of calculated "ideal" weight for height, sex and age. A. Children 1-9. Circles represent white; dots, colored subjects. B. Children 10-19. Circles represent white; dots, colored subjects. C. White adults 20 years and over, and D. Colored adults 20 years and over. Circles represent males; dots, females.

of the subjects recorded intakes less than 30 per cent above actual basal requirements as calculated on the basis of calories per square meter of body surface for age and sex. Several were below this basal requirement. Nevertheless, only a part of these subjects who were on such reduced intakes were as much as 20 per cent below their predicted "ideal" weight; many were over that weight, some by as much as 30 per cent. In Figure 1 these relationships are shown for each subject individually.

Perhaps, in view of the findings described above, the recommended allowances may have been based on a population more obese as a whole than is necessary or perhaps desirable. Ours is in general a lean population.

Some error has undoubtedly been introduced by using "moderate" as the degree of activity of all the subjects. However, it was felt that with a large group of a general population this would introduce less error than an attempt to determine by relatively inaccurate methods the degree of probable energy expenditure of each individual. In general, the population was not characterized by lethargy or a lack of physical energy, such as would be expected had there been as great a deficiency of calories as there appeared. As has been indicated, many of the subjects were employed in rural and farming occupations, continually engaging in moderate to heavy activity without evidence of disability. Others, such as the children, exhibited the usual activity of such subjects of average nutrition. Many of these subjects must have been among those who recorded deficient consumption according to the standards used and, while there were undoubtedly some who were lacking in energy and were functionally deficient, the number does not seem to have been greater than in any general population of this size.

One of the results of a deficiency in energy is a lowering of the basal meta-

bolic rate and it might be suspected that this had occurred in those who failed to show any effect of what appear to be grossly deficient diets. However, such tests as have been made in this area fail to reveal significant evidence of such a depression and though some such effect is possible it seems unlikely that it can be the sole explanation for the lack of correspondence between body weight and the recorded calorie intake.

The best objective evidence of nutrition with respect to energy is the body weight. Examining the mean weights we find that the observed mean weights are equal to or greater than the predicted in 8 of the 20 age and sex groups of subjects. In only 2 of these groups, however, is the calorie intake equal to the recommended allowances. In the 6 other groups the calories are significantly below the recommended allowances. The 2 groups in which the calories are up to the recommended allowances are the white children 1 to 3 and 3 to 6. How colored children of the same ages were able to equal their predicted weight although significantly deficient in calories is unexplained. It might be thought that this was accomplished at the expense of a slower rate and attainment of growth, but this is unlikely because the mean height is equal to that of the whites in each group. A difference in activity is not a likely explanation. It is, of course, possible that errors in recording food intake were greater in the colored group. Two meals a day only were common among them and they may have more often forgotten to record food eaten between meals. In the 1 to 2 year olds a number may have gotten breast milk which was not included in the food consumed. All these conditions may have obtained in the whites too, but probably to a less degree than in the Negroes.

The white and colored females over

21 and colored girls 16-20, subjects whose mean weight was not below normal standards in spite of great deficiencies in calories, exhibited a considerable variation in body weight as revealed by the standard deviation. This variability, emphasizes the existence of considerable numbers of *obese* as well as greatly *underweight subjects* in the former groups, the value for mean weight representing the balance of these two extremes. This in turn suggests the existence of significant factors in calorie-weight relationship other than the supposed calorie requirement. It also suggests the possibility that such standards of requirements are incorrect.

Little of an unusual nature was found in the relative proportion of protein, carbohydrate, and fat in the diets, either in terms of grams, of calories, or as per cent of total calories. The proportion of fat as per cent of total calories is at the higher levels of the average range of such intakes while that of protein is in the lower range. Expressed in the same way, the proportions of fat in the case of the colored subjects are smaller than in the whites, reflecting perhaps the difference in incomes in the two groups in view of the characteristically high cost of fats. There is a corresponding increase in the proportion of carbohydrate but, curiously, instead of a decrease in the proportion of protein as might also be expected there is an actual increase in protein as per cent of total calories. This does not, however, signify a satisfactory or adequate intake of protein in the colored subjects. Rather the contrary is true as shown by the mean intake in grams which reveals inadequate intake in most groups. It is merely that the total calorie intake is so low that even inadequate amounts of protein constitute a higher proportion of calories than in the white group with their higher intake in grams.

An interesting feature is revealed by

the median intakes of carbohydrate, fat, and protein which are significantly and characteristically greater in the males compared with the females in the 13-15, 16-20, and 21+ age groups. This difference is proportionately greatest in the case of protein in which a maximum difference of over 90 per cent is found between white boys and girls of 13-15. However, the age group at which the greatest difference is found varies according to the dietary element. For carbohydrate the greatest difference in the white subjects is between the males and females of 16-20. For fat it is greatest at the ages 13-15 and 21+. For protein it occurs at 13-15. Similar differences might perhaps exist in the younger years but at these ages the sexes have not been separated. In the Negroes somewhat the same differences are found but of a much smaller degree, reflecting, perhaps, the lower absolute levels of intake. Nevertheless for protein a very significant difference is found in most groups and only in the males at ages of 13-15, 16-20, and 21+ is the protein intake at a minimum satisfactory level.

SUMMARY AND CONCLUSION

The methods, procedures, and techniques which have been used in a survey of the nutrition of a rural community in Middle Tennessee (Wilson County) have been described. The survey, which was conducted on a universe basis, included some 1,200 subjects of all ages and sexes, both white and colored, whose nutritional status was determined by a record of food intake, a history and physical examination, and various laboratory tests. The characteristics of the area and the population are given and the results of the survey as it relates to the energy factor (calories). The status of nutrition with regard to this factor was determined principally by the measurement of food consumption and the measurement of body weight

though such accessory indications as history of loss of weight, estimate of amount of subcutaneous tissue, etc., are included.

The findings reveal a moderate to severe deficiency (deficit) in energy (calorie) intake as measured and recorded, compared to the recommended allowances of the Food and Nutrition Board of the National Research Council. With this there was found a significant and often severe deficiency in mean body weight. Not all subjects were abnormally underweight however, even among those whose intakes ap-

peared greatly deficient and many were actually obese. Reasons are given for suggesting that the deficiency of calories is not as great as it appears and that in part this may be because the recommended allowances with which the intakes have been compared are unnecessarily high. Errors in the recording of food intake may be responsible in part but cannot explain all the apparent deficiency.

IMPASSE IN PROCUREMENT AND ASSIGNMENT SERVICE?

IN the past few weeks newspapers and magazines have indicated a public interest in the shortage of physicians in some sections of the United States, and not long ago a Senatorial committee, as part of its man power deliberations, undertook hearings on this subject. From the tenor of published articles it is evident that there is criticism of what has been done in war utilization of physicians, of the way it has been done, and of those who have done it. There is, too, a general tendency to blame physicians as individuals and as groups, and to lay upon the Procurement and Assignment Service an ill-founded charge of lack of foresight.

Now, beyond a doubt, there is room for criticism; and one might well question the wisdom of appointing such a body, made up solely of professionals-at-interest and tied up with representatives of local, state, and national medical organizations as Procurement and Assignment Service seems to be. Still it is the instrument the Government chose and one must not lose sight of the excellence of what has been accomplished in difficult and complex circumstances. Thus it must be remembered that although Procurement and Assignment Service was appointed to meet the needs of the military services, of civilian practice and institutions, and of public health, in so far as these needs relate to the work of physicians, dentists, and veterinarians, *it was not invested with one iota of authority to compel service in any military capacity or civilian category or to say to the Army and Navy that they might have so many physicians and no more.* Yet in spite of this lack of authority, Procurement and Assignment Service has been able to meet the calls of military forces for about one out of every two physicians under 45 years of age. Inasmuch as only approximately one out of every five males of the general population in this age group has been called for military service, this is not a bad showing for physicians. As to whether or not that number of physicians is necessary for the military services is a question which Procurement and Assignment Service has had no right to answer. The military services asked for them and got them, and, under the terms of its appointment, Procurement and Assignment Service would have been subject to deserved criticism if they had not been furnished.

On the whole, that organization did not find it difficult to meet this call for medical officers. Physicians, in various proportions in the different parts of the nation, responded promptly, for there was the enticement of adventure, the glamor of a uniform, the urge of patriotism. But as the time approaches to arrange, as nearly as possible, for an equitable distribution of the physicians who remain in civilian practice, Procurement and Assignment Service's lack of authority becomes evident and its service less effective. In civilian medical service there is no glamor for the physician, no sense of adventure; no opportunity for decorations, and no basis for telling the son what Dad did in World War II. Nor would the physician, by such voluntary re-allocation, accumulate any backlog for post-war prestige and preferment. On the contrary, he would, after the war, be considered to have been a stay-at-home and, during the war, would invite a lowered income, irregular hours, and inadequate facilities. He would be forced, practically, to make a new start in life, with the old practice, built over a period of ten to thirty years, thrown into the laps of those who remained undislocated. He would be required, too, to pay last year's large taxes out of this year's shrunken income. It is not likely that in these circumstances physicians are going to volunteer for this unprofitable and gloryless sacrifice, and at present neither Procurement and Assignment nor any other agency may require them to do this.

And there the situation rests for the moment, with some axes being ground and some sparks flying. It is, obviously, only one part of the general man power problem, but even if all man power were drafted, which seems unlikely in the near future, problems inherent in allocation of physicians would vary somewhat from those of placing industrial workers: The latter would be sent to jobs; the former, to practices. The one would provide a definite wage; the other, an uncertain income. In the meantime, if the shortage of physicians in the United States as a whole, or in parts of it, is sufficiently serious to constitute an action-demanding national problem, certain provisions and arrangements would need to be considered. One of these is the possible necessity of vesting in some authority, which sees both military and civilian needs for physicians, the power to set an upper limit on the ratio of medical officers to the strength of the military forces and to establish a minimum ratio of physicians in practice per unit of population in civilian areas. Consideration, too, would have to be given to public health needs. Ratios would inevitably be lowered, perhaps in all categories, as the military forces grow, for, while Military Paul must be paid in physicians, there is a limit beyond which Peter Public may not be robbed for this purpose. A second thing deserving consideration is that this same agency—possibly Procurement and Assignment Service, broadened and freshened in all its ramifications by the infusion of a public perspective into its now essentially medical one—that this same agency would probably have to be given, finally, the authority to draft physicians for all purposes, drawing first on those communities where the ratio of physicians to population is high, physicians thus called being utilized to meet military necessities, public health demands, and medical service needs in the medically distressed areas.

Finally, in connection with civilian medical service, other practical provisions would have to be given thought: An administrative agency, salaries for physicians drafted into such duties, equipment, a mechanism for the collection of fees and the utilization and disposal of such fees—a thousand and one details. In keeping with our conviction that in both war and peace there should be but one operating health agency of the federal government, we recommend, for this administrative

function, the United States Public Health Service. And heaven help that Service if there is such a job, and the job falls to them, for it would be a thankless task, hectored, as the administrators would be, by ultra-conservatives on the one hand and exhorted by crackpots on the other.

As to whether or not it is necessary or wise to put any or all of these measures into effect depends, of course, upon the acuteness and extent of the problem. As regards a government-operated medical service, action should be taken only if the national emergency is serious enough to justify the institution of state medicine as supplementary to private practice.

EPIDEMIC KERATOCONJUNCTIVITIS

HEALTH officers, physicians in industry, ophthalmologists, public health nurses, especially those in industrial plants, and in fact public health workers in general would do well to go on an alert in regard to epidemic keratoconjunctivitis. Comparatively recently, this eye condition has made its appearance in various parts of the United States, particularly in large industrial plants, and in certain areas has interfered with production. The etiology, epidemiology, and treatment are not yet clearly cut, though definite progress is being made.

To the ordinary observer the condition is a severe conjunctivitis, beginning in one eye and not infrequently involving the other. There is but little pus though considerable lacrimation, with edema and congestion of the lids and conjunctiva. Usually the preauricular gland on the affected side is painful and enlarged. More characteristic of keratoconjunctivitis, and of serious import, is the fact that in the majority of cases there are corneal opacities. These are not difficult to demonstrate with the slit lamp. They result in some current impairment of vision and, although a fairly high proportion clear up, in an indeterminate number of instances the opacities remain long after the acute condition has disappeared. The question of their permanency is one which cannot at the moment be answered.

Sufficient work has been done to indicate that the organisms ordinarily causing conjunctivitis are not responsible for this apparently new disease. Sanders, of the College of Physicians and Surgeons, Columbia University, who reports the recovery of a virus from cases of epidemic keratoconjunctivitis, has carried it through tissue culture and continued it in mice. On neutralization tests against this virus, sera of patients affected with the disease have evidenced a rising antibody content as the disease passes its acute phase and enters into the convalescent period.

How the disease is transmitted remains in the field of speculation. Inasmuch as a fairly high proportion of cases have occurred in persons such as welders and mechanics, whose work may expose them to eye injury, there is a suspicion that a foreign body in the eye, or previous eye irritation may act as a contributing factor. It has been suggested, too, that the high proportion of cases seen in eye injury is due to the fact that the ophthalmologist's hands have become infected from some unrecognized case and that the irritated eye is subject to infection when a normal eye would not be; and there is some evidence which indicates that if an eye clinic has one such case, it is likely to have a number of others. As against this previous-injury and infection-at-eye-clinic hypothesis, is the observation that many cases occur in office workers, or occasionally in housewives, where

there has been neither eye injury nor visits to an eye clinic. There seems to be no difference in the attack rate in males and females when calculations are made on the basis of persons at risk. However, in any given epidemic, there are likely to be more males than females because in most industrial plants men predominate.

As indicated in a letter published elsewhere, the Neurotropic Virus Committee of the Army is interested in this condition, and physicians who encounter cases or suspected cases are urged to report them to the local health officer who, in turn, should advise the state health department. The latter may obtain the aid of the Virus Committee, which would not only insure careful study of the condition, but also sound advice as to the best known control measures. It is rather serious to advocate the isolation of five hundred to a thousand individuals engaged in war work, when in the majority of instances they are able to carry on to some extent. On the other hand, there is reason to believe that if the first few cases are promptly and rigidly isolated, and if auxiliary measures are instituted, a serious outbreak may be prevented. Auxiliary measures consist in an intensive search for missed cases and in scrupulous disinfection of hands and instruments in the eye clinic. In treatment, various measures have been advocated. These vary from cold compresses to sulfathiazole ointment. None is specific.

Here is a problem which will test not only the ingenuity, but the research and control potentialities of many who are interested in or responsible for the public health.

LETTER TO THE EDITOR

TO THE EDITOR:

Among some of the growing problems, which have confronted both health officers and industrial physicians in this country during the past year, has been that of epidemic keratoconjunctivitis—called by some “ship-yard conjunctivitis.” The disease is apparently new to this country but it has appeared in epidemic form, both on the West Coast, and in the East (and perhaps elsewhere) during the short space of a few months. During this period, however, much has been learned—to which recent articles by Hogan and Crawford¹ and by Sanders² testify. This information is not general as yet and apparently epidemic situations can develop insidiously in factories before the nature of the conjunctivitis in its potential seriousness is recognized.

To my knowledge the disease is not reportable in this country and because of this and other obvious reasons it

seems wise to bring it to the attention of your JOURNAL. It is earnestly requested that if new outbreaks, or suspected outbreaks, of this disease (epidemic keratoconjunctivitis) should occur, notification of this fact be made to Dr. Murray Sanders (Department of Bacteriology, College of Physicians and Surgeons, 620 West 168th St., New York, N. Y.). Dr. Sanders has been assigned by the Board for the Investigation of Epidemic Diseases in the U. S. Army to study this problem and to assist in the control of this disease.

A DAY OF HEALTH EDUCATION

Any meeting of professional workers that succeeds in imparting to the participants an increased appreciation of the value, the usefulness, and the timeliness of their efforts is decidedly worth while. This was achieved at the Annual Health Education Conference, held in New York City on November 17, 1942, under the auspices of the New York Academy of Medicine. The recent conference marked the third time in as many years that health educators representing the official and voluntary health, medical, and social agencies in the Metropolitan area foregathered as guests of the Academy to "review the objectives of health education and to plot a straight course toward them." The basic theme of the 1942 Conference dealt with the intensive wartime industrialization of the nation's communities and the health implications involved. Five timely and thought provoking papers were presented upon this thesis in which the problems of nutrition, physical and mental disease, and accidents were considered. Each speaker succeeded in giving a very clear concept of the wartime health problems of industry, from the angle of health education, and their conclusions were a decided stimulus to further thinking and current program planning.

The opening or "theme address" was delivered by Cassius Watson, M.D., Medical Director of the American Telephone and Telegraph Company. This

valuable presentation emphasized the importance of occupational disease and industrial hazards in relation to the successful pursuit of the war effort. Dr. Watson called for an extension of immunization procedures among the working population and directed attention to two factors that loom large in the efficient operation of industrial establishments—fatigue and the emotional instability of employees. The speaker also discussed the value of thorough pre-placement physical examinations and the need for focusing our efforts upon certain diseases that are becoming increasingly threatening, notably brucellosis. Dr. Watson clearly outlined those elements in the health program that demand priority rating while the nation is at war.

Otto A. Bessey, Ph.D., Director of the Public Health Research Institute of the City of New York, contributed a practical and illuminating paper entitled "Food and Nutrition in the Home and the Work Place." This paper stressed the magnitude of the problem of poor nutrition and outlined methods by which this problem is being met in various places. Among other topics covered in Dr. Bessey's discussion were the importance of employing a trained nutritionist to direct feeding in plants and schools, the necessity for providing an adequate amount of time for lunch, and the increasing recognition being given to in-between-meal feeding and its effect on the efficiency of the worker. The speaker warned the audience to keep its sense of values during the current "nutrition boom" and to turn a deaf ear to

Please address samples of printed matter, comments, or other editorial contributions to the editors at One Madison Avenue, New York, N. Y.

promoters of food preparations and enthusiastic groups given to exaggerations and elaborate claims. Dr. Bessey also directed a critical dart toward food caterers who ply their wares for profit with little regard for or appreciation of good nutrition. The preparation of home-packed lunches for working men was cited as one element in the better nutrition program upon which education is needed. It was stated that 90 per cent of the food consumed in industrial plants is home prepared and packed in lunch boxes. One important recommendation made by Dr. Bessey was that the nutritionist employed in plants should work in collaboration with the medical division.

"Disease and Handicap Detection and Control in Industry" was the subject of a paper presented by Leonard Greenburg, M.D., Executive Director of the Division of Industrial Hygiene of the New York State Department of Labor. This highly pertinent contribution included a consideration of absenteeism and the diseases chiefly responsible for loss of time: respiratory infections, digestive disorders, and others. The problem of physical defects as a cause of rejection for industrial employment was also explored by the speaker. Dr. Greenburg pointed to the urgent need for programs of rehabilitation—"a need that is important in times of peace as well as in times of war." It was the contention of the speaker that voluntary health agencies can and must assume a major rôle in helping, through education, to control the problem of disease in industry. Dr. Greenburg's presentation was decidedly challenging.

A paper by Lydia G. Giberson, M.D., Psychiatrist of the Home Office Medical Staff of the Metropolitan Life Insurance Company, was devoted to the subject: "Mental Problems and Morale in Industry." The relation of the mental state of employees to the maintenance of industrial production was convinc-

ingly demonstrated in this direct and practical analysis, which included a discussion of various neurological conditions, psychoneuroses, maladjustments, and the "twin scourges" of industry—absenteeism and fatigue. It was abundantly evident that the type of industrial psychiatry advocated by Dr. Giberson—essentially educational in character—can go a long way toward solving the problem of effectively utilizing maladjusted individuals in industry.

The final address of the Conference was delivered by Harold R. Bixler, Director and Member of the Executive Committee of the National Safety Council. Mr. Bixler's paper was entitled "Educational Methods and Control of Accidents in Industry." Following a general discussion of the magnitude of the industrial and home accident toll, the speaker outlined ways and means of "selling safety" to management and employees on the basis of patriotic, economic, and humanitarian appeals. Among the specific educational measures advocated for the promotion of safety were: job training, conferences, contests, campaigns, awards, and so-called safety stunts. Mr. Bixler's recommendations were practical and could readily be adapted in any program looking to permanent and effective safety promotion.

The presentation of the various papers was followed by an open discussion, and a general summary of the day's proceedings was excellently outlined by Iago Galdston, M.D., Executive Secretary of the Medical Information Bureau of the New York Academy of Medicine. One of *Credit Lines'* editors (D. B. A.) presided throughout the meeting.

The Academy and its Committee on Medical Information deserve the thanks and appreciation of all in attendance at this well organized and stimulating meeting. It is hoped that the papers presented—all of which were marked by wise and timely counsel—will be made available later in printed form.

They should help the health agencies to adapt their current programs to pressing wartime needs and opportunities for service.

A selection of papers delivered at the 1941 Health Education Conference has recently been published in book form under the title: "A Venture in Public Health Integration." Copies are available from Columbia University Press at a cost of \$1.00 each.

NOTES ON RECENT HEALTH PUBLICATIONS

The volume of health education materials reaching the editors of this section of the JOURNAL has markedly decreased during recent months. Perhaps fewer booklets and other publicity items are being produced as agencies suffer the loss of personnel—or perhaps health departments are devoting their energies to more pressing needs in the field. Regardless of the cause, we are glad to say that the diminution in volume has in no way been accompanied by a diminution in the quality of the printed materials received. We have, for instance, just reviewed with interest and admiration the following publications:

1. A series of leaflets on tuberculosis, published by the Medical Department of the Westinghouse Electric and Manufacturing Company. Eight leaflets have been developed on the subject covering diagnostic procedures, signs and symptoms of the disease, methods of transmission, protective measures, nutrition in relation to recovery, treatment of the disease, and the possible increase in mortality from tuberculosis due to war conditions. These leaflets have many attractive aspects. The text of each is forthright, though certain statements here and there would perhaps be questioned by some authorities. Details of color, layout, illustration, and composition have all been thoughtfully and skillfully handled. It strikes us that the idea of breaking up the subject

matter into short leaflets is an interesting departure from the usual practice of presenting the subject as a whole within the scope of a single publication. According to the Westinghouse plan, these leaflets are to be distributed to employees at two week intervals. Will readers gain more by way of this "installment plan" or would a "massive dose" of information be more practical? It would be interesting to know how the employees respond. We recommend this excellent series and commend the enterprise of the commercial organization responsible for them. Copies of the leaflets may be secured from the Westinghouse Medical Department, East Pittsburgh, Pa.

2. The sixth number of the U. S. Public Health Service Workers' Health Series bears the title "Bill Gets the Works." This is a remarkably clever interpretation of the procedures involved in a physical examination and is easily the best of the Workers' Health Series produced so far. Written in a popular conversational style, this booklet will convince employees of the importance of physical examinations and will dispel the impression that "a check-up is just one of those things that the plant 'Doc' has to do to earn his pay." The simple illustrations are "just right" and help to make this a consistently amusing and instructive publication. Copies of "Bill Gets the Works" are available from the Superintendent of Documents, Washington, D. C., at a cost of 5 cents each.

3. Workers in the field of safety education are assuredly attuned to the times—ample evidence of which is seen in a booklet issued by the Greater New York Safety Council entitled, "You and Your Horse." Since many companies have parked their delivery trucks for the duration and replaced them with horse-drawn vehicles, it is well to have authoritative advice available on how to "care for your horse and operate your

wagon safely." Even if you are not faced with a return to horse and buggy transportation, you will thoroughly enjoy reading this booklet which includes among its contents information on such subjects as how to tether your horse, how to make him "back up," how to handle nervous horses, and how to apply auxiliary halters. "Whoa, Dan"—while we tell our readers that this booklet is available from the organization mentioned above, 60 East 42nd Street, New York, N. Y., at 5 cents per copy. "Gid-dap, Dan."

4. Excluding the usual syndicated health columns, newspapers—with a few notable exceptions—are not given to featuring health news. Occasionally, however, special supplements on the subject are published jointly by health or medical agencies and newspapers. With the current emphasis on physical fitness, it is surprising that these supplements do not appear more frequently. An unusually good example of this type of publicity was sponsored recently by the Philadelphia County Medical Society and the *Philadelphia Record*. In twenty pages of tabloid size, the cartoon-strip technic is used to popularize first aid procedures, accident prevention, nutrition, communicable disease control, and personal hygiene. This supplement has considerable "reader interest" chiefly because it avoids the essay or feature story method of presenting health information and utilizes instead the simple, to-the-point approach that is inherent in the cartoon medium. The execution of the drawings and the authentic captions accompanying them show that this supplement was painstakingly worked out. Any health educator armed with a copy of this supplement could no doubt readily convince local editors to undertake a similar venture. Copies of the supplement may be had by writing the Philadelphia County Medical Society, Philadelphia, Pa. We compliment the Public Relations Com-

mittee of the Society and the staff of the *Philadelphia Record* upon rendering a helpful service to the people of the community.

5. Another effective health agency-newspaper venture was sponsored a short time ago by the Public Health Federation of Cincinnati and the *Cincinnati Post*. This consisted of a series of twenty-five articles admonishing citizens to "Be a Health Warden." The series was keyed to the theme that many local doctors are entering the armed services and that individuals must assume responsibility for safeguarding their health. Some of the titles in the Health Warden Series were: Let Your Heart Speak, Show Your Teeth, The Art of Blowing Your Nose, and Babies and Battles. It is reported that the series was enthusiastically received by readers of the *Post*.

6. From the Harlem Tuberculosis and Health Committee of the New York Tuberculosis and Health Association comes a historical report entitled "Twenty Years of Community Health Work." This statement recounts the activities of the committee year by year, and one finds in it an inspiring record of service on behalf of the people of Harlem. The report is conveniently organized and written in an earnest and direct style. Of especial interest is the cover which bears a well balanced type arrangement and an arresting illustration. Copies may be secured from the New York Tuberculosis and Health Association, 386 Fourth Avenue, New York, N. Y.

7. An "A-B-C" interpretation of the Kenny Technic may be gained by reading a folder issued by the National Foundation for Infantile Paralysis under the title, "Principles of the Kenny Method of Treatment of Infantile Paralysis." By listing only the essential facts underlying this form of therapy and by including a few simplified drawings, this publication does an excellent

job of simplification. It should be particularly useful in explaining the Kenny Technic to lay groups. Write to the Foundation at 120 Broadway, New York, N. Y., for copies.

8. The American Social Hygiene Association has sounded its call to the public to enlist in the fight against syphilis and gonorrhea on Social Hygiene Day, February 3, 1943. A neat, well planned folder with the heading "Social Hygiene Takes Battle Stations," outlines various activities that may be undertaken to rally support and to inform the American people about the dangers of venereal disease. The Association suggests many ways of obtaining publicity and will furnish prepared talks, films, literature, exhibits, radio material, and other publicity aids for use in connection with Social Hygiene Day. The Association's publicity staff is certainly adept at preparing lively and informative promotional materials.

POSTERS WITH "PUNCH"

Here we go again on what must appear to be our favorite subject for comment—posters. This medium was never more popular than now: witness the contests that are sponsored, the exhibits that are held, and the financial grants that are made—all for the purpose of stimulating artists to sharpen their technics, to create posters with a "punch." Here, then, are a few more observations on the subject:

"A poster is a form of commercial art—it has something to sell—and its style must be determined by that plain fact. In designing a poster, remember that it must get its idea across in the time that it takes an express train to pass a water tank. It is not meant to be hung on a wall and admired at leisure, or to serve as an illustration in a magazine. And so it cannot afford to flirt with modernistic or abstract effects. It must say what it has to say all at once, right now, and all in the foreground where

the eye can take it in at a glance. Consequently, the successful poster presents a few, carefully chosen words and objects held close to the front plane rather than receding into the background where the quickly passing eye cannot possibly follow. For the same reason, colors must be used in large areas rather than in small details—which is why a good poster looks almost as well in a black and white reproduction as in its original form."

With these facts in mind, we turn to two sets of posters on the venereal diseases—one of which comes from the Venereal Disease Control Officer of the Third Naval District, Lieut. Commander M. Wishengard; the other from the American Social Hygiene Association. The Navy has developed thirteen posters dealing with the prevention and treatment of syphilis and gonorrhea. The art work of each is simple—there are no illustrations aside from decorative border designs in which certain Naval symbols—anchors, ships, ropes, waves, and the like—are reproduced. Two or three colors are used in each poster and they have been selected so as to achieve the most effective combination of tones and hues. The text of each poster is compact and forceful. It was pleasing to find that there was no straining to clutter up these messages with the overworked military motif. In sum, these posters are unusually well done—artistically and textually.

The American Social Hygiene Association has produced six venereal disease posters for display in industrial plants. They measure 11 by 14 inches and are reproduced in two colors. The copy of each is appropriately brief and the illustrations are pleasing. These posters should amply fill the bill for they are admirably done in a style that should appeal to the man behind the machine. Write to the Association at 1790 Broadway, New York, N. Y.—50 cents per set.

Incidentally, we learn that one agency

that has issued many venereal disease posters in which the symbolic motif has prevailed has now discarded this approach and will henceforth revert to "true and literal representations." Why? Because the bulk of the population did not understand symbolic designs.

AN EDITORIALETTE:

HEALTH EDUCATION'S PART IN WINNING THE WAR

The public health profession of America has never faced a greater challenge than today. Any war brings public health problems of enormous variety and magnitude. War, famine, pestilence, and death are still inseparable companions. But this war far exceeds all others in its public health implications.

Wars are not won conclusively by conquering armies or by invading homelands. They are won finally by destroying the will of the conquered peoples to fight back. No better implements for this purpose exist than malnutrition, tuberculosis, the ravages of epidemic disease.

It is the heavy responsibility of the public health profession to guard the health of the workers at home so that their efficiency may be kept at a maximum, to protect the entire population from loss of stamina through manifest illness or lack of robust health, and to protect the armed forces from exposure to health hazards outside the boundaries of their cantonments and from worry over the health of their families at home.

This is a large order under existing circumstances. It is an order, the filling of which will require more health education than ever before.

Since the objective of health education is to improve health behavior, and since so much preventable illness and premature death in this country today is a result of improper health behavior and incorrect health attitudes, health educators share as largely as any other

branch of the public health profession the heavy responsibilities of helping to win the war on the home front.

Our responsibilities are graver today and heavier than ever before. We must prevent in this nation, if we can, some of the underlying causes of defeat in any nation; to remedy, so far as we can, some of the reasons for defective health behavior in this nation; and to solve, so far as is within the power of our most earnest efforts, some of the problems confronting all health educators.

One of the greatest of these problems has been the confusion which exists with respect to the values and technics of modern education when applied to the field of public health. Stemming as it does from the engineering, medical, and related professions, public health has been slow to appreciate fully the potential contributions of education. Education too has been slow in developing health teaching methods and accepting the importance of health teaching as one of its primary objectives. Between the two professions of public health and education has been the barrier of differing professional "lingo." This barrier has at times assumed the characteristics of an insulating double brick wall. But a few hardy souls in each profession have had the courage and patience to run around the barrier, listening and asking questions of the other group and returning to their own group with gems of wisdom interpreted in their own language. Soon the curiosity of each group was aroused and we now find educators being invited to advise with public health officials and health officers being invited to advise with educators. It would seem that this age-old barrier is about to be breached.

One of the most significant steps toward clearing confusion in the field of public health education is the emergence of a report from the APHA Committee on Professional Education on the educational qualifications of health educa-

tors. This committee has described clearly and briefly the values of health education both in schools and health agencies. Most important of all, perhaps, it has concluded that health educators, whether employed by schools or health departments or both, are essentially educators and need full training in both education and public health. Finally, it has listed the academic training which seems most desirable for professional preparation in this important field. This report will soon be ready for publication in its preliminary form in the JOURNAL.

Meanwhile, the professionalization of health education has already been advanced immeasurably through the efforts of this committee. It has distinguished between health education, information, and propaganda. It has defined the proper place of publicity in health education. It has shown the health officer how he may use the skilled health educators to the best advantage. It has formed the basis of a merit system examination for some state departments of health.

Health educators must play an important part in winning the war. This is a cause even greater than we have faced before. It permits no trifling. Confusion as to the status, functions, and training of health educators is being reduced by an increasing rapport between the two great professions of education and public health. A great advance will be made when educators and public health authorities can agree on the functions, responsibilities, values, and training of those professional people who wish to devote themselves to the field of health education.

This editorialette was contributed by William P. Shepard, M.D., Assistant Secretary and Pacific Coast Welfare Director of the Metropolitan Life Insurance Company. It is based on Dr.

Shepard's remarks at the opening session of the 1942 Health Education Institute. We are grateful to Dr. Shepard for his fresh and penetrating appraisal of the rôle of health education in world affairs.

MAGAZINE ARTICLES AND BOOKS

Recent popular magazine articles on health or of medical import:

"Heart Disease and You." Peter J. Steincohn, M. D. *The American Mercury*. December, 1942.

"Protect Your Family from T.B." Edwin R. Levine, M.D. *Parents' Magazine*. December, 1942.

"Hemorrhoids." Maxine Davis. *Good Housekeeping*. December, 1942.

"Animals as Allies." Priscilla Jaquith. *Coronet*. December, 1942.

"What You Don't Know Won't Hurt You." Richard Wright. *Harpers Magazine*. December, 1942.

"The Biologist Looks at Man." By Julian Huxley. *Fortune Magazine*. December, 1942.

"Quick Repairs for Broken Bones." Elsie McCormick. *The Reader's Digest*. December, 1942.

(The above is not presented as a complete list and the articles cited are not necessarily recommended.)

Current publishers' lists are replete with books with a medical or health flavor. They range from novels and humorous essays to the more scientific type of statement. As our readers may wish to buy or borrow some of these books, we give you herewith titles, authors, publishers, prices, and brief "quotes" concerning each:

Big Doc's Girl (a novel). By Mary Medearis. Published by J. B. Lippincott Company, \$2. "A chronicle of a small-town doctor and his family—has freshness and a thoroughly genuine quality."

Insides Out. By John Mason Brown. Published by Dodd, Mead and Com-

pany, \$2. "Anyone who has done time in a hospital will enjoy this laugh provoking book about surgery, doctors, nurses, visitors, pills, and needles."

The Art of the Healer. By Bernard Aschner, M.D. Published by the Dial Press, \$2.75. "Concerns a new system of medicine—constitutional therapy—which the author hopes may endow the healing art with new powers."

Science in Progress. Edited by George A. Baitsell. Published by Yale University Press, \$3. "Reports the latest developments in several fields of science, including medicine."

How To Be Fit. By Robert Kiphuth. Published by Yale University Press, \$2. "Shows how to get into 'fighting trim' in a few short weeks."

The Microbe's Challenge. By Frederick Eberson. Published by the Jaques Cattell Press, \$3.50. "Timely information for the average reader on home-front killers—flu, infantile paralysis, plague."

Adventure in Blood Transfusion. By Bertram M. Bernheim, M.D. Published by Smith and Durrell, Inc., \$2.50. "The wondrous story of a great surgical achievement."

Silent Enemies. By Justina Hill, M.D. Published by G. P. Putnam's Sons, \$2.50. "The story of the diseases of war and their control."

Love Against Hate. By Karl Menninger, M.D. Published by Harcourt, Brace and Company, \$3.50. "An analysis of the war of emotions within the human being."

Memoirs of a Guinea Pig. By Howard Vincent O'Brien. Published by G. P. Putnam's Sons, \$2. "For everyone who has been to a doctor, knows one, or is one."

JOTTINGS

A statement worthy of prolonged applause: "An author who writes of scientific matters for the public has a twofold obligation: accuracy and truth must not be distorted; the reader must

not be misled by unconfirmed information. Such writings should be ruthlessly criticised by experts long before the type is set." (Justina Hill, M.D., Johns Hopkins School of Medicine.) Certain popular articles published lately have flouted these desirable principles. . . . Historical note: The first American newspaper, the short-lived Boston *Publick Occurrences*, carried in its first issue, dated September 25, 1690, two paragraphs of health news. The comments concerned the smallpox epidemic in Boston. . . . Slips that pass in the night: Copies of a first aid handbook were recently distributed with this errata note attached—"Please open your copy at page 58 and strike out the words 'tincture of iodine (2%)'. This is an editorial error; it should read 'calamine lotion.' . . . We are glad to learn that the Executive Board of the A.P.H.A. has authorized the appointment of a Committee on Accidents which will be concerned with industrial, home, farm, and public accidents. Personnel of this committee will be announced later by the Committee on Administrative Practice. This step is of especial interest to health educators, inasmuch as it will open new fields for using educational technics. The new committee is expected to work in close collaboration with the Home Safety Advisory Committee of the National Safety Council. . . . As a contribution to the national nutrition program, the Aetna Life Insurance Company has released a two-reel film entitled "Vitality for Victory" in which the normal nutritional needs of industrial workers and other groups are stressed. . . . *The Lancet*, British medical journal, ever a source of inspiration, pays this tribute to public health nurses: "Let us now praise District Nurses and the Committees that begat them, for they are daughters to the aged, mothers to the motherless, sisters to them in labour, whose hands, holy but sterile, heal the

sores of the outcast and the blains that have broken, clip the beards of the ancients and the nails of them who cannot bend or see, who perform the task of the menial and are paid with the thanks of the lowly and the privilege of service, who come like sun to the prisoned and song to the cottage, who bring the news of the village and the jest of the market, and bear a message from one who is sick to another, who ease the way of the dying and the crown of the baby, who watch the going of life with *stertorous gliding* and its coming with bulge and recession, oft keeping vigil by candle, who must walk in men's ways alone, warily treading between the footmarks of gossip, the ruts of malice and the paths of the partisan, who oft see the dawn of a day, but know not the labours it's bringing. O apostles of soap and sanity, O black-bagged friars of country lanes, Angels on Pushbikes, I salute you, District Nurses!" . . . An excellent paper entitled "The Use of Radio in Health Education" was recently presented before the Annual Institute for Education by Radio. David Resnick, publicity director of the National Society for the Prevention of Blindness, spoke on this

topic. His talk is an interesting and informative analysis of what is being done through radio in the health education field—including references to the broadcasts sponsored by the American Medical Association, the New York Academy of Medicine, and other leading agencies. Mr. Resnick lays stress upon the importance of having health broadcasters work more closely with radio experts in planning health talks for radio audiences. He also analyzes the actual and potential effect of the war situation on the use of radio time by voluntary organizations in the health field. Copies of Mr. Resnick's address may be obtained by writing to the Society at 1790 Broadway, New York, N. Y. . . . Many interesting health education projects are being worked out by United China Relief—including the formulation of a basic language for the dissemination of medical and health information. . . . The American Academy of Pediatrics has set up a special committee to establish standards which should be met by all physicians engaged in child health services. . . . A quotation from Surgeon General Parran: "Public health will be the spearhead for future international agreements."

BOOKS AND REPORTS

History of the School of Nursing of the Presbyterian Hospital, New York 1892-1942 — By *Elleanor Lee, A.B., R.N., Assistant Professor of Nursing, Department of Nursing, College of Physicians and Surgeons, Columbia University. New York: Putnam, 1942. 286 pp. Price, \$3.50.*

Cherished by its graduates as the embodiment of their accomplishments and traditions, this book will also be cherished by nurses everywhere as a history of nursing in its broadest and deepest sense. Herself a teacher of nursing history, the author has made a contribution which will be welcomed by other teachers and students of this subject.

A remarkable feature of the book is the author's success in tying up the history of a great institution, and the biography of certain leaders in nursing, with that of the profession as a whole; with the development of medicine and public health; with the civic and social growth of the community which it serves. Historical facts are interspersed with choice bits of reminiscence such as are usually scattered about in minutes, in note books and training school records, and in the minds of older members. These have been painstakingly assembled and delightfully presented. To the younger nurse, they give a vivid picture of an earlier period against which to place her own opportunities and experiences. The older nurse is sent back to the good old days with the feeling that the diary of 1897 must have been her very own.

The history of the school naturally divides itself into two periods, that under the guidance of Miss Maxwell and that under Miss Young. While the lengthened shadows of these two are

constantly visible, the contributions of others have been given individual mention and consideration. One is also conscious of the understanding and staunch support of the medical staff and the board of governors, whose part is seen in every undertaking of the school and in every related movement.

Without attempting to describe in full the contents of the book, some features of special interest may be noted. For instance, in the development of the curriculum, changes have taken place only after careful study of the situation elsewhere and in line with sound principles clearly stated and practically followed. In the words of Miss Maxwell "We must note the signs of the times, keep abreast of modern thought and make the conditions and equipment of this school the best in the country." The progressive steps taken in pursuance of these aims are clearly indicated. These gradually resulted in affiliations with Columbia University until in 1935 the School of Nursing became the Department of Nursing under the faculty of the School of Medicine.

Interesting reading are the chapters on the Alumnae Association and on Visiting Nursing and Social Service. Most thrilling of all perhaps is the record of service in three wars. It was to this school that the American Red Cross turned, in the Spanish-American War, for a leader to establish the first group of trained nurses in an army camp in this country. In this undertaking, Miss Maxwell was joined by others of her staff. The record established at that time was carried forward into the first world war and the present conflict.

In addition to the history proper there is a chronological list of events,

and an appendix containing much valuable material. The excellent set-up with its numerous illustrations adds to the value and charm of the book. We venture to predict that in future annals of the school this volume will be counted as one of its great achievements.

HARRIET FROST

Why We Have Automobile Accidents—By *Harry R. De Silva*. New York: Wiley, 1942. 394 pp. Price, \$4.00.

Reasons why health officers should be interested in the automobile accident problem have been brought out in meetings of the American Public Health Association. In this book, De Silva summarizes in interesting fashion the information on this subject which is available at the present time. While recognizing that numerous factors enter to complicate the problem, for example, the road, the car, and the pedestrian, the author emphasizes the predominant rôle played by the driver. Accordingly we find among the sixteen chapters of the book, such subjects as the following: skill; safety-mindedness; speed; incompetent drivers; training and examining drivers; and control of licensed drivers.

An abundance of statistical material is cited which, as in most discussions of automobile accidents, is rather inadequate. The trouble is the lack of information on such factors as the populations and mileages subjected to specific risks, e.g., at different hours of travel, different kinds of roads, etc. The health officer would be in a comparable predicament if, for example, he could not compare the white and Negro death *rates* from tuberculosis, but only the deaths, because the exposed white and Negro populations were unknown. The paucity of information on population exposed to risk is recognized by De Silva and other writers; but one sometimes wonders whether, with more liberal employment of index numbers, better use could not

be made of such traffic data as are available.

There are informing chapters at the end of the book on preventive programs, and the administrative problems underlying these.

All in all, this is an important book. It should be read widely.

A. W. HEDRICH

Psychology Applied to Nursing—By *Lawrence Augustus Averill*, and *Florence C. Kempf*. (2nd ed.) Philadelphia: Saunders, 1942. 455 pp. Price, \$2.50.

The first reaction of most nurse educators to textbooks on specialized subjects "applied to nursing" is: What has been left out or written down in order to make this material apply to the field of nursing?

Undoubtedly, a selection and adaptation of subject matter from the field of psychology are desirable in teaching student nurses, but to this reviewer such a textbook is a sorry compromise for a well qualified instructor who is a specialist in this field and who works with the other faculty members in the school of nursing to enrich the psychological content of the whole curriculum. As one reads these chapters, he is also struck by the fact that the same goal might be attained by offering student nurses an elementary course in general psychology with applications in the ward and clinical experiences under the guidance of a qualified consultant psychologist.

The revised edition of the original textbook (1938) approaches its problem under five headings: The Regulation of Our Behavior, The Mechanisms Behind Our Behavior, The Relationship of Learning to Behavior, Behavior in Specific Life Periods, and Behavior as Related to Emotional Life, and there has been added material dealing with the emotional reactions and psychology of childhood, as well as a revision of

the "thought problems" at the end of each chapter. There is no doubt about the practicality of these "thought problems" when discussed under the leadership of a psychologist, and the general text of this book is very readable.

Public health nurses will find the last chapter (Chapter XV) interesting and all the reading lists helpful.

DOROTHY DEMING

Bonnie's Baby Brother and How He Grew—By *Elizabeth Rider Montgomery*. New York: Stokes, 1942. 95 pp. Price, \$2.00.

This book contains an attractive series of photographs with a simple and brief text made by a mother for her 5 year old daughter which presents pictorially the rapid growth and development of a new baby brother, at successive 2 month periods, during his first year of life. It portrays the rapidly changing and increasing relationships between the new baby, his sister, and the parents.

A main purpose of the book is to prepare an older child for the arrival of a new member of the family. This is neatly and casually done in picture and text. Section II, "Two-Month Old," perhaps should include an illustration of attempts of vocalizing instead of placing this illustration in the "Four-Month Old" group.

Although this book should help prepare any child for a new addition to the family, naturally it cannot be expected to accomplish this by itself. Of primary importance are the attitudes of and preparation given by the parents to an older child long before birth of a new baby. More attention than necessary is given to the anterior fontanel and care needed to protect it. Slightly more attention and emphasis than may be warranted is given to the older child's responsibility for helping with the baby's care. One gains the impression that the mother may be fearful that her daughter may not love the baby and so

compensates by overdoing the matter of preparing the older child.

In other respects the text is beautifully presented. Children from 3 years of age should enjoy and appreciate this book. No doubt young mothers preparing for their first-born may find the book informative as to changes in growth and development to be expected in the first year of their child's life.

GEORGE S. FRAUENBERGER

Nutrition and Chemical Growth in Childhood. Vol. I. Evaluation—By *Icie G. Macy*, Springfield, Ill.: Thomas, 1942. 432 pp. Price, \$5.00.

This first of two volumes presents the results of ten years of intensive clinical and biochemical investigation of normal children. The study was soundly conceived and was carried out with infinite care for scientific detail. Volume I consists of detailed discussion of factors involved in such a comprehensive study, of methods used, and of records kept. The book also gives brief glimpses of summarized results. The second volume will concern the interpretation of these results and, it is to be hoped, the complete data obtained in the studies.

The detail of the descriptions in the present volume will make the book a most helpful reference for those engaged in similar studies. The summarized results are a valuable contribution in themselves and serve to whet the appetite for Volume II, which will contain the detailed results.

GENEVIEVE STEARNS

The Modern Attack on Tuberculosis—By *Henry D. Chadwick and Alton S. Pope*. New York: Commonwealth Fund, 1942. 95 pp. Price, \$1.00.

This concise manual sets forth all the information essential in the formulation of a program for controlling tuberculosis in any community. All phases of

the disease are efficiently discussed, including epidemiology, case finding, diagnosis, and treatment. The simple practical manner in which the authors present the epidemiological aspect is of particular interest to all public health workers. Too frequently control programs exclude practical application of all the information available from the epidemiological viewpoint.

The importance of hospitalization is properly emphasized. Case finding is discussed thoroughly. Basing their views on a wide experience in the examination of different population groups, valuable information is given concerning the groups most productive of new cases of tuberculosis. The unimportance of the mass examination of school children as a means of case finding is stressed.

The last chapter deals with the various steps to be taken in organizing a community campaign for the eradication of the disease. The forecast expressed by the authors for the eradication of tuberculosis may be somewhat optimistic; nevertheless, such a goal should spur the interest of all.

This book should be in the library of every health department and used as a handbook by health officers, public health nurses, and all others interested in tuberculosis control. R. S. GASS

Microbiology of Meats—By L. B. Jensen. Champaign, Ill.: Garrard Press, 1942. 252 pp. Price, \$4.00.

This monograph is based on many years of experience in applied bacteriology, the most recent of which have been spent as Chief Bacteriologist of one of America's largest meat-packing concerns in Chicago, Swift and Company. Dr. Jensen therefore speaks from much experience when he reviews what goes on microbiologically "in the yards." *Microbiology of Meats* is divided into 12 chapters.

As should be the case, the monograph

starts with Introduction and History followed by discussions of such subjects as nitrate curing, gaseous fermentation of meat products, green discoloration, action of microorganisms on fats, ham souring, microbiology of fresh meats, sausage, bacon, and other meat specialties. Control of microorganisms in the meat-packing plant is discussed in considerable detail, attention being given to contributions of microorganisms which might be made to meat products by such things as paper, sawdust, and wooden apparatus. The final chapter deals with food poisoning problems on which much more light is needed in some quarters.

The book is well documented with references to the literature. It should be in the libraries of all food technologists and especially of all those who work for meat preservation concerns. It is also a fine example of the art of book making. F. W. TANNER

Emergency Care — By Marie A. Wooders, R.N., and Donald A. Curtis, M.D. Philadelphia: Davis, 1942. 560 pp. Price, \$3.50.

This is an excellent textbook on emergency care, intended for the use of nurses. It should be just as useful to those who have taken the Red Cross First Aid and Home Nursing courses.

The authors use many effective diagrams, tables, and photographs. Especially useful in this period of emergency should be the unusually good material assembled in the section on General Emergencies. The sections on Hospital and Occupational Emergencies are also well handled.

The book is helpfully indexed and there is a useful set of questions, with a bibliography at the end of some of the chapters. It is to be regretted that the authors did not see fit to have this worth while feature at the end of all chapters. One questions the necessity of the chapter on the Organizations of

the Army and Navy, but these are only minor criticisms.

Altogether for the purposes for which this book is intended, the reviewer feels that the objectives have been accomplished. HARRY E. UNGERLEIDER

The Meat You Eat—The report of the New York State Trichinosis Commission. Legislative Document 35, 1942. 94 Broadway, Newburgh, N. Y., 1942. Paper, 141 pp.

The Meat You Eat is the second and final report of the New York State Trichinosis Commission which was created in 1940, and extended in 1941 with the object of recommending methods of preventing trichinosis in New York State. The present report, while not as complete as the original one entitled *Meat for Millions*, nevertheless is interesting in relation to the matter of trichinosis. A brief history of trichinosis and a report of recent outbreaks is presented and trichinosis developments during 1941 are reported by Dr. W. H. Wright of the National Institute of Health. The recommendation by the commission that the state adopt compulsory meat inspection, locally administered, has been approved. Previous recommendations of the commission were also adopted in 1941. The present report does not deal exclusively with pork, and embraces the subject of meat, its inspection and its place in the dietary. This report is a useful contribution to the subject of trichinosis, and if widely circulated to the laity should help educate the public without frightening them about pork, or detracting from its value as a foodstuff.

HARRY MOST

Psychology in Nursing Practice—By Philip L. Harriman, Lila L. Greenwood and Edward Skinner. New York: Macmillan, 1942. 483 pp. Price, \$3.25.

Here is a psychology written for both nurses in training and nurses in service,

by a professor of psychology, a professor of education, and a nurse who is a teaching supervisor in a hospital in addition to being an assistant instructor of therapeutics to medical students. Such a combination of authors accounts for the scientific accuracy, broad outlook, practicality and up-to-dateness which this textbook displays.

The philosophy of the contents is the same as that of *A Curriculum Guide for Schools of Nursing* (1937 edition). The pattern of organization into four units is also the same as that recommended in the *Guide*. One chapter deals with the Nature and Methods of Psychology, five chapters with the Biological and Social Basis of Behavior; four chapters with Essentials of Learning, and six chapters with Personality and Adjustment.

Particularly good is the chapter entitled "The Behaving Organism" with its excellent diagrams and graphs drawn from a wide field of recent research. The chapter ends with a good description of the physical and personality changes brought on by old age and senility. The treatment of the chapter entitled "The Atypical and the Socially Maladjusted" with its case histories is especially valuable for nurses.

The chapter on the Psychology of Mental Deficiency and Mental Disorder, by Robert M. Lindner, Ph.D., of the U. S. Public Health Service, opens up some interesting theories about the causes of mental deficiency. Here Dr. Lindner expresses his views as to the possibility of alteration of the germ plasm in syphilis. In the chapter on the learning process, the statement that a pan of water on the radiator is sufficient as a device to raise the humidity of a room is open to question.

There are footnotes on nearly every page, an extensive series of questions and exercises, and a list of selected references at the end of each chapter.

The appendix contains monthly rec-

ords for judging personality and professional efficiency, suggested reference books for students of nursing in the various fields of psychology including mental hygiene, and an excellent vitamin chart. There is an index of subject and an index of names.

Nurses in training and in service have a treat coming if they have to use this textbook, which, in addition to being on a high intellectual plane, embodies the fundamentals of all the types of psychology and ties them up with the actual patients and problems nurses have in the hospital or in the home.

EVA F. MAC DOUGALL

The Mentally Ill and Public Provision for Their Care in Illinois—By Stuart K. Jaffary. Chicago: University of Chicago Press, 1942. 214 pp. Price, \$1.25.

This is one of the many good monographs in the University of Chicago Social Service series. The approach is essentially social but with liberal informative data on the legal and institutional aspects. The focus is well expressed in the introduction, "The present study lies in the field of public responsibility for the care of the mentally ill."

The medical profession as well as the general public should find this work of distinct educational value. Insanity is not only a term of sociolegal origin, but it is also a problem essentially for the public services and the legal channels which largely control the public approach to it.

Medicine had better realize that psychiatry is a neglected problem child in the medical school curriculum. The public had better look to its legal administration in probate work as this study shows amply the indifference, apathy in the two approaches.

We cannot agree with the writer that psychiatric treatment is so costly that it is beyond the reach of all save a small number of wealthy persons (page

175). This is over-argument for public control. Hospitalization plans, such as in Cleveland, have bridged nicely the short periods of institutional major therapy. Then too the needed development of psychiatric service in general hospitals will lessen the need for a huge expansion of public facilities which practically are never sought out by the patient and used then as a last resort.

MAURICE A. R. HENNESSY

Microbiology and Man—By Jorgen Birkeland. New York: F. S. Crofts & Co., 1942. 478 pp. Price, \$4.00.

This volume contains four sections. The first (130 pages), on Fundamentals of Microbiology, contains nine chapters on general properties of microorganisms, their physiology, etc., including a historical introduction, a chapter on methods of study, and several on such phenomena as variation and effects of chemical and physical agents on microorganisms. The second section (49 pages) contains four chapters on Infection and Resistance, but one discusses the spread of infectious disease, and one epidemiology and the use of biostatistical methods. Section three, the largest in the book (185 pages) describes over thirty Common Infectious Diseases. The diseases are generally discussed under three or more headings, an example being whooping cough: symptomatology, etiology (synopsis of *Hemophilus pertussis*), pathogenesis of the disease, immunity, epidemiology, prevention, and control. The last section of 77 pages on the Microbiology of Food, Milk, Water, Sewage, and Soils contains a chapter on each of these topics as well as one on Food Toxemias and Food-borne Infections. A condensed synopsis of the orders, families, and tribes of the Class Schizomycetes, a glossary, a list of pertinent publications, and an index complete the volume.

The author has a good grasp of his subject and writes interestingly and

concisely, sometimes all too briefly. The book is relatively free from factual error, and is generally up-to-date. Although there are several excellent pictures and graphs, it would be much improved by more illustrations, tables, and specific instances. Laboratory methodology is almost entirely absent. The material is developed primarily for the student of medical and public health bacteriology, although the author has aimed at a general treatise.

MARTIN FROBISHER

Nursing History—By *Minnie Goodnow*. (7th ed.) Philadelphia: Saunders, 1942. 495 pp. Price, \$3.00.

This is very readable history. Much has been added to this seventh edition from Miss Goodnow's further study of source material and her personal observations in many countries. The author has not only dealt with developments in nursing in the countries where most progress has been made, such as England and America, but she has included interesting sketches of developments in all European and Asiatic countries that can boast of a nursing program.

Beginning with nursing in ancient times, Miss Goodnow traces the outstanding developments in nursing, point-

ing out how nursing has been influenced by war, religion, and the change in the status of women. With the rapid changes of the present emergency, it is regrettable that this new edition could carry the reader no further than the threshold of World War II. The weakest part of this history is in the field of public health nursing although the author speaks of this field as "the most important future development in nursing."

Instead of using space to give cases to illustrate the need for social service, a few case histories to illustrate good family health work would have given a truer picture of public health nursing. The participation of the government in public health nursing and its far reaching influence on standards through the nursing bureaus of the U. S. Public Health Service and the Children's Bureau should have been stressed.

While Miss Goodnow gives due credit to the work of the Red Cross in its contribution to nursing in other countries, the place played by the Rockefeller Foundation in its extensive program for nursing education and public health nursing in coöperation with government agencies throughout the world is given very little attention.

MARGUERITE WALES

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Small Wisp Points Gale's Direction—In New York State, the September death rate from tuberculosis was 43.5, an increase of 14 per cent above that of September, 1941. The last increase of such magnitude occurred in 1917, the first year of our participation in the first, or youth's size, World War.

ANON. Health Conditions in New York State—September, 1942. *Health News*. 19, 45:189 (Nov. 9), 1942.

Odd Items from Everywhere Department—Did you know this? "One interesting and little known fact about drinking, is that water taken on an empty stomach may lead to greater thirst, as the liquid passing quickly to the tissues, may provoke a diuresis of greater volume than the liquid drunk."

ANON. Editorial Notes. *J. Roy. Inst. Pub. Health & Hyg.*, 5, 10:183 (Oct.), 1942.

Just in Case—What was done in a built-up region that was heavily bombed on consecutive nights makes gruesome but useful reading. Great need was found for temporary housing accommodations, and the sanitary problems created by the nightly exodus were many and difficult, as any health administrator would anticipate.

ANON. Public Health Aspects of Intensive Air Raids on a Built-up Area. *Pub. Health*. 56, 1:7 (Oct.), 1942.

Good Record Proudly Presented—Eight points of an attack against cancer as developed in a 13 year old county program are convincingly reported upon. Outstanding in the educational phase is the approach to teen age school children.

ADIE, G. C., and CHARLTON, H. R. Cancer Control in Westchester. *J.A.M.A.* 120, 10:752 (Nov. 7), 1942.

Against Venereal Disease in Industry—Ways to find and refer for treatment all venereal cases among industrial employees so that patients may continue on the job without danger to themselves or their fellow employees is a timely topic. All health workers, as well as those to which it is addressed, will profit by reading this committee report.

ANDERSON, O. L., *et al.* Recommendations to State and Local Health Departments. *J.A.M.A.* 120, 11:828 (Nov. 14), 1942.

More Anti-venereal Effort Needed—Blood tests of military candidates have revealed 200,000 men with syphilis. Current reports indicate that only 40 per cent of them have been placed under treatment. Of the men in the services 4 of each 100 contract venereal disease in our communities. These are some of the indications that we should be doing plenty more than we are at present about this major threat to our war effort.

ASELMEYER, A. J. Civilian Measures for the Control of Venereal Diseases in World War II. *J.A.M.A.* 120, 12:880 (Nov. 21), 1942.

Sick Cats and Pneumonia—Speaking of virus pneumonias—as who isn't these days—it seems that cats, too, are succumbing to an epidemic caused by a virus (but one that cannot pass through filters, resembling in this respect the elementary bodies of psittacosis). A number of instances of contact between sick cats and people

who have developed atypical pneumonia have been noted.

BAKER, J. A. A Virus Obtained from a Pneumonia of Cats and Its Possible Cause of Atypical Pneumonia in Man. *Science*. 96, 2499:475 (Nov. 20), 1942.

Miscellaneous Notes on Whooping Cough—Pertussis antitoxin can prevent whooping cough if given prior to the onset of coughing, but is of little value once the "whoop" is on. Nasopharyngeal cultures are superior to cough plates as diagnostic aids. These are only two of many important findings reported in a series of three related papers, published together.

BULLOWA, J. G. M., *et al.* Pertussis Immunity with Toxin and Antitoxin; (and) BROOKS, A. M., *et al.* The Method of Nasopharyngeal Culture in the Diagnosis of Whooping Cough. *J.A.M.A.* 120, 12:886 (Nov. 21), 1942.

Epidemiologic Note—Incubation periods in 37 attacks of poliomyelitis varied from 5 to 35 days and averaged 12.2 plus or minus 1.1 days.

CASEY, A. E. The Incubation Period in Epidemic Poliomyelitis. *J.A.M.A.* 120, 11:805 (Nov. 14), 1942.

As Doctors Become Scarce—For a half million farm people, the Farm Security Administration's medical care program has brought medical and hospital services within the range of thin, rural pocketbooks. If the plan is found practical in that obviously difficult situation, it would seem worth studying for its possibilities for adaptation to the millions of urban people who also need medical care.

GODING, H. K. Better Health for Farm Families. *Pub. Health Nurs.* 34, 11:616 (Nov.), 1942.

Educators Please Note—Breaking a self-imposed rule about direct quotes, here are five for your edification: "When the people were shown it was unprofitable to tolerate tuberculosis, something was done—and done in a

hurry." "The public was not interested in tuberculosis, it was not interested in health; it was interested in the cost of the disease." "The change in emphasis from 'a clean tooth never decays' to 'improving beauty and attractiveness through good teeth' sent untold numbers of young and old to dentists." "This thought influenced people because they were interested in beauty and not health (or truth)." "There appears to be valid reason for challenging interest in health as even an important reason for healthy practices."

GUDAKUNST, D. W. The Interest of the Public in Health. *Canad. Pub. Health J.* 33, 10:490 (Oct.), 1942.

Feeding Our Neglected Toddlers—Number nineteen in an outstanding series of articles on nutrition (referred to in this bibliography at the beginning) this paper on infant feeding demands that it be called pointedly to your attention. Though we have done reasonably well nutritionally by our babies, we're not doing right by those past infancy, concludes this author.

JEANS, P. C. The Feeding of Healthy Infants and Children. *J.A.M.A.* 120, 12:913 (Nov. 21), 1942.

Colleges with TB Case Finding—Minnesota, Western Reserve, Yale, Michigan, Vassar, Pennsylvania began it. Now more and more colleges are doing something about tuberculosis, the leading cause of death of college age women and men. There is, however, still a widespread neglect of this health administrative essential among our institutions of so-called higher education.

LIGHT, C. E. Tuberculosis in College Students. *Am. Rev. Tuberc.* 46, 3:227 (Sept.), 1942.

Balm for Smoking Mothers—Nicotine was found to be excreted in the milk of all mothers who smoke

cigarettes, but the amounts were so small that there was no demonstrable effect upon the nurslings. As so few mothers can be induced to nurse their babies nowadays, this reassuring finding is of less moment than it would have been with the breast feeding practices of a generation ago.

PERLMAN, H. H., *et al.* The Excretion of Nicotine in Breast Milk and Urine from Cigarette Smoking. *J.A.M.A.* 120, 13:1003 (Nov. 28), 1942.

Public Health's Step-Child—Thirty-nine varieties of state cancer control programs were tabulated and summarized. Only about a million and a quarter dollars seem to have been expended last year on this still largely neglected service, but interest in doing something increases.

SCHEELE, L. A. Present Status of State Cancer Control Programs. *Pub. Health Rep.* 57, 43:1599 (Oct. 23), 1942.

For Distant-visioned Health Officers—Care of the aged being about the last thing on the conscience of most health workers today, you may question the utility of including articles on geriatrics in this bibliography. However, the subject is brought to your attention from time to time because of the hunch that it is destined some day to become an important part of health administration. This paper points out that healthy old people can serve in industry as substitutes for absent soldiers.

THEWLIS, M. W. Care of the Aged. *J.A.M.A.* 120, 10:749 (Nov. 7), 1942.

ASSOCIATION NEWS

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Samuel L. Andelman, M.D., 4141 N. Clarendon, Chicago, Ill., Asst. Surgeon (R), U. S. Marine Hospital U. S. Public Health Service
 Charles W. Anderson, M.D., C.M., Inyo County Health Officer, Bishop, Calif.
 E. Dwight Barnett, M.D., 3325 Chanate Road, Santa Rosa, Calif., Director, Sonoma County Health Dept.
 Charles D. Beale, D.O., 105 Center St., Rutland, Vt., Health Officer
 Donald A. Campbell, M.D., Newton County Health Unit, Neosho, Mo., Health Officer
 Paul C. Campbell, Sr., M.D., Cumberland County Health Dept., Fayetteville, N. C., Director of Venereal Disease Control, U. S. Public Health Service
 John T. Foley, Jr., M.D., M.P.H., 10 Ticknor St., South Boston, Mass., Director, Venereal Disease Control Division, Boston Health Dept.
 Frank M. Hartsook, M.D., Court House, Mount Gilad, Ohio, Morrow County Health Commissioner
 William E. Holmes, M.D., 1801 7th Ave., Scottsbluff, Nebr., Local Health Officer
 Virginia F. Howard, M.D., M.P.H., Box 269, Carthage, Miss., Director, Leake County Health Dept.
 Anna R. Manittoff, M.D., 3941 Pine Grove Ave., Chicago, Ill., Health Officer, Chicago Health Dept.
 Wilber J. Menke, M.D., 111 Dean St., Woodstock, Ill., Dist. Health Supt.
 Gertrude Nielsen, M.D., 101 E. Eufaula, Norman, Okla., Director, Cleveland County Health Unit
 Francis H. Redewill, Jr., M.D., M.S.P.H., Pennington County Health Unit, Rapid City, S. D., Health Officer
 Isidore Sackowitz, 4 No. Co-op Circle, Jersey Homesteads, N. J., Health Officer, Board of Health
 Emil Schmick, Board of Health, Verona, N. J., Health Officer
 Harry S. Stahr, M.D., Health Dept., 116 Quincy St., Hancock, Mich., Director
 Willard J. Stone, M.D., Marion County Health Dept., Salem, Ore., Health Officer
 George G. Taylor, State Health Dept., Elkhart, Ill., Supervisor, Venereal Disease Control

Felix A. Tornabene, M.D., M.S.P.H., 51 Fox St., Aurora, Ill., Dist. Health Supt.

Laboratory Section

Calvin E. Corey, M.A., Cottage Hospital, Galesburg, Ill., Bacteriologist, Western Branch Laboratory, State Dept. of Health
 Axel R. Gronau, M.D., 4942 W. Pine, St. Louis, Mo., Physician, City Health Dept.
 Alexander Hollaender, Ph.D., National Institute of Health, Bethesda, Md., Senior Biophysicist
 Ralph V. Hussong, Ph.D., 123 N. Washington Ave., Danville, Ill., Dairy Bacteriologist and Chemist, Sugar Creek Creamery Co.
 Livius L. Lankford, Health Dept., City Hall Annex, Dallas, Tex., Bacteriologist, Health Dept. Lab.
 George F. Luippold, Army Medical School, Washington, D. C., Officer in charge of Laboratory, Typhoid Research Unit
 Veronica F. Martos, M.S., Boehne Hospital, Evansville, Ind., Research Bacteriologist
 Grace M. McCrary, 625 Oakwood, Webster Groves, Mo., Director of Laboratory, St. Louis County Board of Health
 Major F. C. Mortensen, Station Hospital, Jefferson Barracks, Mo., Sanitary Officer, U. S. Army
 Frank E. Nelson, Ph.D., Bacteriology Dept., Kansas State College, Manhattan, Kans., Assoc. Prof. of Bacteriology
 David F. Rogers, A.B., Monsanto Chemical Co., 1700 S. Second St., St. Louis, Mo., Bacteriologist
 Mary R. Smith, M.S., State Dept. of Health Laboratory, Oklahoma City, Okla., Bacteriologist
 Edward A. Steinhaus, Ph.D., Rocky Mountain Lab., U. S. Public Health Service, Hamilton, Mont., Assoc. Bacteriologist
 Virginia Tlapak, M.S., DeGiverville Ave., St. Louis, Mo., Bacteriologist, St. Louis Health Division
 Louis H. Weiner, B.S., 3638 Broadway, Chicago, Ill., Director of Laboratory, The Borden Co., Chicago Milk Div.
 William A. Womer, M.D., Dept. of Health, New Castle, Pa., Director, Health Dept.

Vital Statistics Section

Raymond S. Behrle, 405-608 S. Dearborn St.,

- Chicago, Ill., Representative, Haloid Company
- Bertram J. Black, M.S., 519 Smithfield St., Pittsburgh, Pa., Director, Bureau of Social Research, Federation of Social Agencies of Pittsburgh and Allegheny County
- Carl L. Erhardt, B.A., 69 Grant Ave., Brooklyn, N. Y., Asst. to Registrar of Records, New York City Dept. of Health
- Irving V. Sollins, Ph.D., 54 W. Hubbard St., Chicago, Ill., Senior Public Health Representative, U. S. Public Health Service

Engineering Section

- Pedro P. Azpurua Q, Este 8 No. 123, Caracas, Venezuela, S. A., Engineer, Compania Anomma Riego
- Robert R. Cunningham, B.S., 131½ S. Side Square, Macomb, Ill., Asst. Sanitary Engineer, State Dept. of Public Health
- Robert W. Eddy, B.S., 511 N. 11th St., Lawrenceville, Ill., Sanitary Engineer, Lawrence County Health Dept.
- Richard J. Hammerstrom, B.S., Tulane Univ., Sch. of Med., New Orleans, La., Instructor of Preventive Medicine
- Dorothy Baumes Phelps, M.S., 335 State Office Bldg., Providence, R. I., Sanitary Bacteriologist, State Dept. of Health
- Verdun Randolph, B.S., State Dept. of Public Health, Div. of San. Eng., Springfield, Ill., Sanitary Engineer
- Wilfred K. Rodman, M.S., Box 511, Salem, Mo., Dist. Public Health Engineer

Industrial Hygiene Section

- Clyde M. Berry, Ph.D., State Board of Health, Raleigh, N. C., Asst. Sanitary Engineer (R), U. S. Public Health Service
- Lester V. Cralley, Ph.D., National Institute of Health, Div. of Industrial Hygiene, Bethesda, Md., Asst. Sanitary Engineer (R), U. S. Public Health Service
- David S. Falk, B.S., 1320 Westview Ave., East Lansing, Mich., Ventilation Engineer, Bureau of Industrial Hygiene, State Dept. of Health
- Roberts A. Hearn, M.D., State Health Dept., Little Rock, Ark., Director, Div. of Industrial Hygiene
- Pope A. Lawrence, M.S., 303 E. 10th St., Austin, Tex., Industrial Hygiene Engineer, State Dept. of Health
- Christopher Leggo, M.D., Municipal Courts Bldg., Room 62, St. Louis, Mo., Industrial Hygiene Physician, State Board of Health
- Morgan B. Lewman, 620 S. Third St., Louisville, Ky., Industrial Hygiene Engineer, State Dept. of Health

Food and Nutrition Section

- French Boyd, B.S., 19 Sycamore St., Mooresville, N. C., Consultant, Office of Defense Health and Welfare Services
- Winthrop F. Bronson, A.B., 8321 Drexel Ave., Chicago, Ill.
- Edward J. Czarnetzky, Ph.D., Wilson and Co., 4100 Ashland Ave., Chicago, Ill., Biologist
- Agnes Erkel, B.S., 2258 Knapp St., St. Paul, Minn., Nutritionist, Family Nursing Service
- Cecile S. Hambleton, P. O. Box 1046, Alexandria, Va., Student, William and Mary College
- Thomas C. M. Larsen, State Board of Health, Topeka, Kans., Chief, Milk Sanitation, State Board of Health
- Major Victor E. Levine, M.C., O'Reilly General Hospital, U. S. A., Springfield, Mo.
- Mary Reeves, State Board of Health, Jefferson City, Mo., Nutrition Consultant
- Anna Smrha, B.S., State Dept. of Health, Lincoln, Nebr., Public Health Nutritionist

Maternal and Child Health Section

- Chester J. Antos, M.D., State Board of Health, Jefferson City, Mo., Pediatric Consultant
- John F. Belz, M.D., 3115 N.E. 41st Ave., Portland, Ore., Maternal and Child Health Director, State Board of Health
- Alice D. Chenoweth-Pate, M.D., Cumberland Apts., Louisville, Ky., Director, Div. of Maternal and Child Health, State Dept. of Health
- Lee O. Frech, M.D., 250 North Water, Decatur, Ill., Pediatrician, State Dept. of Public Health
- Paul R. Gerhardt, M.D., P. O. Box 749, Charleston, W. Va., Chief, Bureau of Medical Services, State Dept. of Public Assistance
- Henrietta Herbolzheimer, M.D., 606 S. Fourth St., Springfield, Ill., Field Consultant in Maternity and Infancy, State Health Dept.
- Lenore Patrick, M.D., State Dept. of Health, Charleston, W. Va., Director, Maternal and Child Health

Public Health Education Section

- Marvin F. Carter, 879 Madison St., Memphis, Tenn., Director, Health Education, Memphis--Shelby County Health Dept.
- Ruth E. Heltenen, B.S., 7470 Byron, Detroit, Mich., Social Director and Instructor of Health and Hygiene, Ford Hospital School of Nursing
- Mary C. Leo, A.B., State House, Augusta, Me., Director, Civilian Health Education, State Bureau of Health
- Albertaine P. McKellar, B.S., Cumberland County Health Dept., Fayetteville, N. C., Asst. Consultant in Health Education, U. S. Public Health Service

Myrtle H. Miller, R.N., 401 Estelle, Ferguson, Mo., Staff Nurse, St. Louis County Health Dept.

Cornelia Mulder, Community Service Center, Flint, Mich., Health Educator, Flint Board of Education

Egbert W. Neidig, M.A., 51 Warren Ave. West, Detroit, Mich., Secretary, Health Council of Metropolitan Detroit

Paul A. Teschner, M.D., 535 N. Dearborn, Chicago, Ill., Asst. Director, Bureau of Health Education, American Medical Assn.

Public Health Nursing Section

Frances S. Buck, B.S., R.N., 2411 N. Charles St., Baltimore, Md., Public Health Nursing Consultant, State Dept. of Health

Mary C. Carne, R.N., 124 N. Patrick St., Alexandria, Va., Supervisor of Public Health Nurses, Alexandria Health Dept.

Beatrice M. Clutch, M.A., George Peabody College, Nashville, Tenn., Assoc. Prof. of Public Health Nursing

Sarah E. Daily, R.N., 251 S. Maffit St., Decatur, Ill., Dist. Supervising Nurse, State Dept. of Public Health

Berenice C. Gardner, B.S., 1709 Washington St., St. Louis, Mo., Nursing Consultant, American Red Cross

Sophia A. Jarc, B.S. in N., N. Y. State Dept. of Health, Albany, N. Y., Public Health Nursing Educational Consultant

Lillian Jeffers, 904 S. Second St., Springfield, Ill., Maternity Supervisor, State Dept. of Health

Mary A. Keenan, R.N., 720 Reiscli Bldg., Springfield, Ill., Unit Nurse, State Dept. of Public Health

Virginia E. Knott, R.N., 28 S. Illinois Ave., Villa Park, Ill., Supervising Nurse, DuPage County Health Dept.

Katharine M. Kreizenbeck-Leenhouts, Main St., Mechanicsburg, Ill., Asst. Supervising Nurse, Div. of Public Health Nursing, State Dept. of Public Health

M. Joyce Leslie, Box 1008, Port Alberni, B. C., Canada, Public Health Nurse, Port Alberni Public Health Centre

Mary Ann MacKay, B.S., 204 City Hall, Peoria, Ill., Supt., Visiting Nurse Assn.

Jean E. McNee, Peabody College, Nashville, Tenn., Asst. Prof. in Public Health Nursing

Edna L. Moorhouse, M.A., Main St., New City, N. Y., Supervising Public Health Nurse, State Dept. of Health

Leora R. Neal, R.N., 1906 W. DuBois, Lawrenceville, Ill., Supervising Nurse, Lawrence County Dept. of Public Health

Hazel A. Nordley, Box 387, Crandon, Wis., Public Health Nurse, State Board of Health

Margaret Reid, B.S., 235 E. 22nd St., New

York, N. Y., Education Director, Metropolitan Life Ins. Co.

Edna B. Robinson, P. O. Box 1192, Concord, Calif., Supervising Nurse, Contra Costa County Health Dept.

A. Mary Ross, 3408 Kenwood, Kansas City, Mo., Supervisor and School Nurse, Board of Education

Mary J. Ross, 5660 Kingsbury Blvd., St. Louis, Mo., School Nurse, School District City of LaDue, Mo.

Marguerite D. Rowland, 107 W. Mason Ave., Alexandria, Va., Staff Nurse, Alexandria Health Dept.

Emma Sater, B.S., 210 Corby Bldg., St. Joseph, Mo., Director, St. Joseph Organization for Public Health Nursing

Leone W. Ware, 2020 South Park Ave., Springfield, Ill., Asst. Supervising Nurse, State Dept. of Public Health

Epidemiology Section

Francisco E. Ortega-Canet, M.D., San Lazaro 1212 (altos), Habana, Cuba, Comisionado de Salubridad Publica, Ministerio de Salubridad y Asst. Soc.

William A. Davis, M.D., M.P.H., 331 E. 71st St., New York, N. Y., Staff Member, International Health Division, Rockefeller Foundation

Harry Goldman, M.D., M.P.H., 259 Hanover St., Boston, Mass., Deputy Commissioner, Boston Health Dept.

Ruth L. Green, A.B., 909 McKinley Ave., Oakland, Calif., Junior Public Health Analyst, Oakland Health Dept.

David S. Ruhe, M.D., 840 Cherry St., 605 Volunteer Bldg., Atlanta, Ga., Asst. Surgeon, U. S. Public Health Service

Unaffiliated

Max Gross, M.D., 109 States Ave., Atlantic City, N. J., Director of Tuberculosis Clinics for State of New Jersey

Jerome R. Mulconnery, D.D.S., 325 E. Broadway, East St. Louis, Ill., Dentist, East Side Health Dist.

DECEASED MEMBERS

LeRoy A. Wilkes, M.D., Trenton, N. J., Elected Member 1919, Maternal and Child Health Section

Horton R. Casparis, M.D., Nashville, Tenn., Elected Member 1941, Maternal and Child Health Section

E. G. Buckland, New Haven, Conn., Elected Member 1920, Health Officers Section

S. S. Goldwater, M.D., New York, N. Y., Elected Member 1902, Elected Fellow 1922, Charter Fellow, Maternal and Child Health Section

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

POSITIONS AVAILABLE

U. S. CIVIL SERVICE COMMISSION. Public Health Nursing Consultants, 5 grades. See November *American Journal of Public Health*, or write U. S. Public Health Service, Washington, D. C.

Merit System Council, Oregon State Board of Health and Crippled Children's Division, has announced merit examinations in practically all public health fields. See November *American Journal of Public Health*, or write H. J. Sears, Merit System Supervisor, P. O. Box 88, Portland, Ore.

Indiana State Personnel Division announces that applications may be filed for positions in orthopedic nursing, medical positions (5 classes), and local public health director. See November *American Journal of Public Health*, or write Indiana State Personnel Division, 141 South Meridian Street, Indianapolis, Ind.

Physician, man or woman, as director of Division of Maternal, Child and School Hygiene in southern city department of health. Woman physician with pediatric training preferred, public health experience not essential. To operate prenatal, infant and preschool clinics and promote school health program. Salary commensurate with ability and qualifications of applicant. Apply Box J, Employment Service, A.P.H.A.

Southern state department of health seeks several obstetric and pediatric consultants, requiring a minimum of a year's residency in a specialty, immunity to draft and preferably training in public health. Men and women are eligible. Salary \$300 per month plus travel. Apply Box C, Employment Service, A.P.H.A.

Public Health Engineer and director of Division of Sanitation of a city and county health unit; population 145,000 in the Midwest. Salary \$3,180 and travel allowance. Box E, Employment Service, A.P.H.A.

The Flint Civil Service Commission will consider applications for Executive Health Officer of the Flint Department of Health. Applicants must be medical graduates with a valid license to practise

medicine in Michigan or eligibility for such license; also must have practised medicine and surgery for five or more years and had considerable experience in public health work. There will be no written test, qualifications being judged solely from review of experience, education and training and an oral examination. Present incumbent is on military leave of absence under circumstances which will probably extend for a period of five years. Staff consists of over fifty professional and technically trained employees. Probable salary \$5,400. Inquiries should be directed to Foster B. Roser, Director, Flint Civil Service Commission, City Hall, Flint, Mich.

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, medical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tenn., or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

Public health nurses wanted for two-county unit in Michigan. Must be graduates with minimum of 4 months' public health training or 8 months' training under supervision. Salary \$1,800 per year with travel allowance \$35 to \$41 per month. Must drive and own a car. Address Dr. Koupal, Director Alger-Schoolcraft Health Dept., Manistique, Mich.

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sana-

toria. Open competitive examinations will be held and the resulting lists are expected to be in existence for 2 years or longer. Residence requirements are waived for professional positions.

INDUSTRIAL HYGIENISTS

The Research Section of the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md., needs chemists, physicists, and medical technicians, as well as laboratory assistants in these fields. There is also opportunity for persons without college education, specific training or experience who are interested in such positions. Women now form one-third of the employees in the Research Section.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK, N. Y.

In view of the current active demand for trained and experienced persons in public health it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

M.D., Dr.P.H., interested mental and industrial hygiene, chief of mental hygiene clinic, on staff of psychiatric hospital, speaker, writer, author of books on health, diplomate in psychiatry, professor of psychiatry. Ineligible for military service because of age, healthy, vigorous, able to

work hard, now in private practice; would make sacrifice and accept decent but lower remuneration than present income if he could be employed in war industry, preferably New York, New Jersey, or Connecticut. United States citizen. Had important government job in last war. Speaks and writes several languages. A-504.

NEWS FROM THE FIELD

IMPROVEMENT IN THE TEACHING OF TROPICAL MEDICINE IN MEDICAL SCHOOLS

THE John and Mary R. Markle Foundation has appropriated \$25,000 to the Association of American Medical Colleges to finance a program for the improvement of teaching tropical medicine in the medical schools in the United States and Canada. The development of of this plan has been placed in the hands of a Committee on Tropical Medicine of the association consisting of Henry E. Meleney, M.D., New York University, Chairman, Malcolm H. Soule, Sc.D., University of Michigan, and Hiram W. Kostmayer, M.D., Tulane University. The plan consists of offering to each medical school an opportunity for two members of its teaching staff to attend a 2 months' course in tropical medicine beginning January 4, 1943.

The Surgeon General of the Army has given permission for one representative from each school to attend the course in tropical medicine being given to medical officers at the Army Medical School, Washington, D. C. This course consists of a broad survey of tropical medicine, and is intended for clinical instructors in medical schools.

The Department of Tropical Medicine of Tulane University has agreed to give a special course in tropical medicine in which particular emphasis will be placed upon the laboratory diagnosis, pathology, clinical aspects, and prevention of tropical diseases. This course is intended particularly for physicians who will teach the laboratory aspects of tropical diseases.

Each of these courses can accommodate thirty instructors from medical schools. Travel and living expenses and, in the case of the Tulane Course, a

tuition fee, will be paid from the appropriation of the Markle Foundation. The Deans of medical schools have been asked to nominate instructors to attend these courses, and the response indicates that each course will have a maximum attendance. Preference will be given to the schools whose instructors are now least well prepared to teach tropical medicine.

It is recognized that there is also great need for instructors in medical schools to obtain practical experience in tropical medicine. Preliminary inquiry indicates that such experience can probably be provided in the American tropics later during the coming year. Candidates for such practical experience would be selected from among those who had completed the course at the Army Medical School or Tulane, and other instructors who have had academic training but not field experience in tropical medicine.

The committee of the Association of American Medical Colleges has also interested itself in the collection of teaching specimens and material for the teaching of parasitic and other tropical diseases in medical schools. The Army Medical School, with the coöperation of the National Institute of Health and other institutions, is developing a Distributing Center for such material. Information concerning this Distributing Center is being sent to the medical schools with instruction for the procurement of material either locally or from the Center. It is expected that in addition to laboratory specimens of animal parasites, there may be available certain charts, lantern slides, and motion pictures.

The office of the Surgeon General of the Army has offered to make available to medical schools information which has been collected on the distribution of tropical diseases throughout the world. Plans for editing this material are in progress, and it is expected that maps will also be prepared, and made available to medical schools, showing the world distribution of the important tropical diseases. The Markle Foundation has made an additional appropriation of \$3,000 to the National Research Council for the preparation of this material.

FACTS ABOUT NURSING, 1942

A convenient source book for those who deal with the broader aspects of nursing, especially in their relation to the nation's war effort, has been issued by the Nursing Information Bureau of the American Nurses' Association, 1790 Broadway, New York, N. Y.

Included among the timely data are the number of nurses serving in military, other government and voluntary hospitals and agencies; the number of nurses needed; the number of students enrolled in nursing schools; the distribution of federal funds for nursing education; salary ranges; and the number of auxiliary workers in nursing services. The pamphlet may be ordered from the Book Service, A.P.H.A., at 25¢.

NEW INDUSTRIAL HYGIENE DIVISION IN WASHINGTON STATE

Announcement has been made of the establishment on October 1 of a new Division of Industrial Hygiene in the Washington State Department of Health with offices in Seattle. This was made possible through a coöperative venture with the U. S. Public Health Service.

CHANGES IN ILLINOIS HEALTH UNITS

The Illinois State Department of Health, Roland R. Cross, M.D., Direc-

tor, has announced that four of the Illinois counties designated as health defense zones have recently extended essential local health services throughout the entire zone to take charge of the new county-wide projects set up for the duration of the war. H. O. Collins, M.D., of the Quincy Public Health District, has been appointed defense zone health officer for Adams County, R. C. Farrier, M.D., of the East Side Health District as defense zone health officer for St. Clair County, and N. O. Gundersen, M.D., of the Rockford Health Department for Winnebago County, with Sumner Miller, M.D., of the Peoria City Health Department serving for Peoria County.

This raises to 11 the number of Illinois health defense counties in which state-subsidized local health service is now continuously provided. The state will contribute additional trained personnel to work under the supervision of the newly commissioned medical health officers as has already been done in the counties of Cook, DuPage, Lawrence, Lee, Morgan, Will, and Williamson.

The other 19 Illinois counties which are at present eligible for this service by virtue of their designation as health defense zones are Carrol, Champaign, De Kalb, Edgar, Fulton, Henderson, Kane, Kankakee, Knox, Lake, La Salle, McDonough, Macon, Madison, Marion, Rock Island, Sangamon, Tazewell, and Vermilion.

According to the *Illinois Health Messenger*, of the 91 Illinois counties which at present have no full-time county-wide local health service, 72 are entirely without recourse under existing Illinois law to any legal means of establishing such service.

"QUALIFICATIONS AND CLASSIFICATION OF PUBLIC HEALTH ENGINEERING PERSONNEL"

A report under the above title was presented at St. Louis before the Con-

ference of Municipal Public Health Engineers. It has been suggested by the Section officers of the Engineering Section, A.P.H.A., that the conclusions are worthy of publication. In brief they are as follows:

1. That the report of the A.P.H.A. on qualifications of personnel engaged in the field of environmental sanitation is acceptable.

2. That there should be three main categories of these workers, (a) public health or sanitary engineers, including only those having professional engineering degrees or their equivalent, (b) sanitarians, who may be non-engineering but technical employees working under engineering direction, (c) sanitary inspectors, a title to be applied to those in health department employment who are without adequate prior training or qualifications.

The committee is impressed with the necessity of providing classes of personnel below the level of public health (or sanitary) engineers. They recommend (1) the placing of these non-engineering groups under engineering direction, (2) raising their educational level by in-service training, and by replacement and addition of fully qualified persons, and (3) the achievement of a rational and uniform system of titles in place of the present haphazard designations inherited from the past.

SEVENTH ANNUAL MEETING OF THE INDUSTRIAL HYGIENE FOUNDATION

The Industrial Hygiene Foundation of Pittsburgh recently held its 7th Annual Meeting at the Mellon Institute. The purpose of the Foundation, which is a non-profit association of mining and manufacturing concerns, is to protect the health of industrial workers.

John F. McMahon was appointed Managing Director of the Foundation, succeeding Dr. H. B. Meller who has retired from active management because of ill health. Dr. Meller will continue as consultant.

More than 500 representatives from some 200 industrial concerns and a number of governmental agencies attended the annual meeting, which had for its theme Keep War Workers Well. Andrew Fletcher of New York was re-elected Chairman of the Board and new

members of the Board of Trustees included Ned H. Dearborn, Ph.D., Executive Vice President, National Safety Council, Chicago; Professor Philip Drinker, Harvard School of Public Health, Boston; Lt. Col. A. J. Lanza, M.C., A.U.S., Chief, Occupational Hygiene Branch, and C. D. Selby, M.D., Medical Consultant, General Motors Corporation.

"LESSONS FROM BRITISH EXPERIENCE IN CIVIL DEFENSE"

George Baehr, M.D., Chief Medical Officer of the Office of Civilian Defense, Washington, has recently reported the following observations made on a recent inspection of emergency medical facilities in England and Scotland. These are summarized from *Medical Series Circular No. 20* of the O.C.D.

1. Heavy raids occur invariably at night, bombs now have much greater destructive effect, incendiary bombs are used in much larger numbers and fire is now the most serious hazard.

2. In large cities the field casualty services may handle more than 2,500 casualties during a night raid. All serious casualties are moved directly to hospitals and never to first-aid posts. Heavy raids are apt to be repeated on subsequent nights when the protective forces are exhausted.

3. A large fleet of four-stretcher ambulances is essential for life saving. These could be simply made from used passenger cars on which is mounted a simple ambulance body. The use of trucks has proven unsatisfactory, being absorbed for other purposes, and frequently not reaching the scene of accident.

4. Casualty stations staffed by one or two doctors, several nurses and a variable number of aides and auxiliaries are necessary at or near all hospitals and at places more than a mile from hospitals to care for minor casualties which do not require hospitalization. Many of these are now on a care-and-maintenance basis and are activated only during the raids.

5. In large cities casualty stations need not be more numerous than 1 per 25,000 inhabitants. They should be located about a mile apart. Many of the minor casualties are moved to first-aid posts in sitting-case cars; some walk.

6. First-aid parties or stretcher teams are

not necessary, are a waste of man power and are rapidly being eliminated in England. First-aid at incidents is essentially a function of the rescue parties which extricate casualties from under the debris of demolished buildings. All first-aid parties are being merged into rescue parties. They include a leader, assistant leader and 8 other members and are entirely independent of the fire department. They are a life-saving service related to the medical services concerned in field casualty work.

7. It is necessary to revise the concept underlying first-aid. Almost all raids occur at night, the victims are crushed under the debris of demolished buildings and are either dead or severely injured. Less than a third are slightly injured and can be cared for at casualty stations.

8. Wounds are usually grossly contaminated and need only be covered with a shell dressing until the casualty reaches the hospital. Hemorrhage is usually controllable with a pressure dressing, the tourniquet is rarely employed. Burns are covered only with sterile gauze until the casualty arrives at the hospital. Tannic acid jelly as a first-aid dressing for burns has been discarded because of the dirt which invariably contaminates the burned surface, because the jelly deteriorates rapidly and because tannic acid ignites in the presence of phosphorus when applied to burns caused by the explosion of phosphorus-oil bombs.

9. Traction splints are not used except when the casualty must be transported a long distance over country roads. The darkness and conditions of an air raid make hurried application difficult or impossible.

10. Shock is treated at the incident by prompt administration of adequate doses of morphine, coramine, proper blanketing, administration of fluids and the use of hot water bottles. The use of plasma or blood transfusion is deferred until arrival at the hospital.

11. The presence of a physician at the incident is invaluable but more than one is unnecessary. Physicians with a staff of nurses may supervise more than one incident.

12. The load of casualties is so distributed that even in heavy raids large hospitals rarely receive more than 50 to 100 casualties.

13. A large casualty receiving hospital is often related to one or more peripheral hospitals in the suburbs or in a country district. There are now four base hospital beds for each casualty bed in the cities.

14. On notification that casualties have occurred an express party is immediately dispatched consisting of one rescue first-aid party, one ambulance, one sitting-case car and

one mobile medical unit, the latter consisting of one physician, one nurse and two auxiliaries. In this manner useless movement is avoided and equipment and personnel of the community is carefully conserved.

POSTGRADUATE COURSE IN INDUSTRIAL HYGIENE AT PHILADELPHIA

An 8 weeks postgraduate course in industrial hygiene and medicine has been announced to begin January 5 at the Philadelphia County Medical Society under the auspices of the Committees on Industrial Health of the Society and the Medical Society of the State of Pennsylvania. The course will be directed jointly by the Departments of Preventive Medicine and Public Health of the University of Pennsylvania and the Woman's Medical College of Pennsylvania. Topics listed for study are The Worker and the Job, Learning the Scope of the Field, Physical Factors, Non-occupational Disease Hazards in Industry, Toxicology and Compensation and Medico-Legal Factors.

ARMED SERVICES SET UP TYPHUS COMMISSION

Secretary Stimson of the U. S. War Department announced on November 19 the creation of the United States of America Typhus Commission which is made up of four persons under the chairmanship of Rear Admiral Charles S. Stephenson, Medical Corps, U.S.N. The other members are Lieut. Col. Harry Plotz, Medical Corps, A.U.S., Senior Surgeon Adolph Runreich, Public Health Service, and Major John C. Snyder, Medical Corps, A.U.S.

SOCIAL HYGIENE DAY, 1943

Walter Clarke, M.D., Executive Director of the American Social Hygiene Association, New York, has announced the annual observance of Social Hygiene Day, scheduled for Wednesday, February 3, 1943.

Since the roots of syphilis and gonorrhea are in the home front, Dr. Clarke

pointed out that the observance of Social Hygiene Day would assume more significance than before. He recalled that total absences from duty during the first world war from these infections kept the equivalent of 20,600 men out of the fighting for an entire year. These are the equivalent of the personnel required to man five aircraft carriers and nine destroyers. In wartime he said that the function of social hygiene organizations is to persuade each community to use our weapons against the venereal diseases effectively.

1942-1943 OFFICERS OF IDAHO PUBLIC HEALTH ASSOCIATION

At its Third Annual Meeting, held in Pocatello October 12 to 13, 1942, the Idaho Public Health Association elected the following new officers:

President—A. H. Christiansen, Boise
1st Vice-President—Stuart Robinson, D.D.S., Gooding
2d Vice-President—Mrs. H. J. Maughan, Preston
3d Vice-President—Mrs. Otto Leuschel, Lewiston
4th Vice-President—Mrs. Emma Cloucheck, Twin Falls
5th Vice-President—John M. Coughlin, M.D., Twin Falls
Secretary—H. C. Clare, Boise
Treasurer—Lucy M. Higgins, Boise

ORAL HEALTH GROUP

The Oral Health Group of the A. P. H. A., in session at St. Louis, Mo., in October, 1942, appointed the following officers:

Chairman—C. R. Taylor, D.D.S., Lansing, Mich.
Secretary—Walter J. Peltón, D.D.S., Washington, D. C.

MICHIGAN PUBLIC HEALTH ASSOCIATION

The Michigan Public Health Association held its 22nd Annual Meeting in Grand Rapids, November 11 to 13, and at that time elected the following new officers to serve for the forthcoming year:

President—Emilie G. Sargent, R.N., Detroit
President-elect—Edward D. Rich, Lansing
Vice-President—C. D. Barrett, M.D., Mason
Secretary-Treasurer—Marjorie Delavan, Lansing
Representative on A.P.H.A. Governing Council—W. R. Davis, D.D.S., Lansing

CONFERENCE OF MUNICIPAL PUBLIC HEALTH ENGINEERS

The new officers of the Conference of Municipal Public Health Engineers are as follows:

Chairman—William T. Ingram, A.B. in C.E., Stockton, Calif.
Vice-Chairman—J. Lloyd Barron, C.E., Roslyn Heights, N. Y.
Secretary-Treasurer—Charles Senn, Milwaukee, Wis.
Executive Committee:
 Charles M. Davidson, Louisville, Ky. (1943)
 Alan C. Love, Waco, Tex. (1943)
 Aime Cousineau, Montreal, Can. (1944)
 Leonard Board, C.E., Clayton, Mo. (1944)
 Sol Pincus, C.E., New York, N. Y. (1945)
 Alfred H. Fletcher, Baltimore, Md. (1945)

FORTY-SEVEN DEATHS FROM POISONING IN OREGON STATE HOSPITAL

The press on November 19 and 20 carried dispatches from Salem, Ore., indicating that 47 patients at the Oregon State Hospital for the Insane out of 467 served at an evening meal had died from a poison suspected of being sodium fluoride.

It is stated that all of the patients who ate the meal became ill and that symptoms included nausea, stomach cramps, and paralysis of the legs, with evidence of respiratory paralysis. Studies of the food indicated that rats fed on the eggs taken from the plates of the diners died within a few minutes, though they were not killed by eating eggs from the cans of frozen egg yolk which had been used for the meal. It was suspected that the fluoride had been put into the mixture during preparation in the institution. The first patient died within an hour of the meal and within 6 hours 32 had died.

As a result of the report the Depart-

ment of Agriculture halted further distribution of frozen eggs through its regional offices, pending the conclusion of the investigation at Salem.

TRANSPARENT MAN COMES TO CLEVELAND

Dr. Bruno Gebhard, Director of the Cleveland Health Museum, announces that, through the generosity of Louis I. Dublin, Ph.D., and Homer N. Calver of the American Museum of Health, the Cleveland Health Museum will show during the coming year most of the main items of the former Hall of Man and Medicine of the New York World's Fair. This material includes many items of the Oberlaender Trust Collection, such as the Transparent Man, and others. Public announcement of these exhibits was made at the Second Anniversary Luncheon of the Health Museum on November 20, where W. W. Peter, M.D., Dr.P.H., Associate Professor of Public Health at Yale University, was the speaker on "Keep the Home Fires Burning."

PAUL O. KOMORA IN NEW YORK STATE DEPARTMENT OF MENTAL HYGIENE

Paul O. Komora, associate secretary of the National Committee for Mental Hygiene since 1932, has resigned from that organization to become assistant secretary of the New York State Department of Mental Hygiene at Albany. He was associated with the National Committee for many years, having served as secretary to Dr. Thomas W. Salmon, first medical director of the committee, and later as educational publicity director, editor, research worker, and assistant to Clifford W. Beers, founder of the organization, in the administration of its corporate affairs. The board of directors recently tendered him a testimonial dinner in observance of his 25 years of service with the committee and as a "send off" to his new post, at which Dr. Adolf Meyer presided and

his friends and associates, including many distinguished psychiatrists, paid him tributes.

Mr. Komora served in the psychiatric organization in the U. S. Army in France during the first world war, helped to organize the First International Congress on Mental Hygiene held in Washington in 1930, directed the public relations work of the American Psychiatric Association and the American Orthopsychiatric Association at many of their conventions, and served as administrative secretary of the notable symposium on mental health conducted by the American Association for the Advancement of Science at Richmond, Va., in 1938. He is the author of various articles and reports in this field of public health.

In his new position, Mr. Komora enters upon duties and responsibilities comparable to his previous activities but adapted to the requirements of public service in one of the largest departments of government in a state that has long exercised leadership in the field of mental hygiene. In the major phases of his work he will be engaged in the administrative relationships of the department with the 26 institutions for the mentally sick and defective under its supervision, with other state departments as well as private institutions and agencies active in mental health and social welfare work, and with the public. There are over 100,000 patients in the institutions of the Department of Mental Hygiene. To care for and properly treat this large body of patients requires the services of nearly 500 physicians, over 12,000 ward employees, and over 6,000 other employees. To maintain these patients requires an annual expenditure of approximately \$36,000,000.

FIFTH ANNUAL CONGRESS ON INDUSTRIAL HEALTH

The Council on Industrial Health of the American Medical Association has

announced through the Secretary, Carl M. Peterson, M.D., that the Fifth Annual Congress on Industrial Health, under the sponsorship of the Council, will be held January 11-13 at the Palmer House, Chicago. The meetings are open to physicians and others interested in industrial health. There is no registration fee. The preliminary program can be found on pages 1145-1146 of the *Journal of the American Medical Association*, December 5, 1942.

PROGRESS IN DEFINING STANDARDS FOR TOXIC DUSTS AND GASES

The American Public Health Association is represented on the Committee on Allowable Concentrations of Toxic Dusts and Gases—Z. 37, of the American Standards Association, by J. J. Bloomfield of the National Institute of Health, Bethesda, Md. Mr. Bloomfield's recent progress report on the work of this committee indicates that the proposed American Standard Allowable Concentration of Chronic Acid and Chromates has been approved and will receive early publication. Similar action was taken on the proposed Standard for Mercury.

The committee is currently considering action on standards for Nitrous Gases, for Arsenic, for Carbon Tetrachloride, Lead, Xylol, Formaldehyde, Hydrofluoric Acid, Methanol, Silica, Toluene and Trichlorethylene. The committee has decided for the present not to attempt standards on Antimony and Zinc.

INDUSTRIAL MEDICINE COURSE AT LONG ISLAND COLLEGE OF MEDICINE

Thomas D. Dublin, M.D., Associate Professor and head of the Department of Preventive Medicine and Community Health of the Long Island College of Medicine, Brooklyn, N. Y., reports that the two weeks postgraduate course in industrial medicine given at the college during November has been completed.

Fifty-nine physicians, nurses, and industrial observers from six states registered for the course, including the seminars and clinics. Seven of the students were placed as "interns" in medical departments of industrial firms which offered facilities for a month's practical training. These firms included the American Cyanamid Company, the Lowe Paper Company, the Bell Telephone Laboratories, Consolidated Edison Company, and the New York Telephone Company.

NEW HEALTH UNIT IN WASHINGTON

The health departments of Jefferson and Clallam Counties, Washington, have united to form a joint public health district unit, following a conference of the Washington State Department of Health and officials of these counties and the cities of Port Angeles and Port Townsend. The central office will be located at the court house in Port Angeles, with a branch office at Jefferson County court house in Port Townsend. District offices will be located in other sections of the counties.

PERSONALS

Central States

KURT CARL BECKER, M.D., of Troy, Ohio, has resigned as Health Commissioner of Miami County, to enter private practice in Troy. He will be succeeded, as Health Commissioner of Troy and Miami County by HARRY WAIN, M.D., M.S.P.H.,† of Sidney, formerly Health Commissioner for Sidney and Shelby County.

ARTHUR E. GORMAN,* who has been Engineer of Water Purification in Chicago, Ill., was appointed, on August 1, Chief of the Water Production Section, Power Division, War Production Board, Washington, D.

* Fellow A.P.H.A.

† Member A.P.H.A.

C., on leave of absence from the City of Chicago.

FREDERICK G. HALL, M.D., formerly of Galesburg, Ill., has been named Assistant City Health Officer of Long Beach, Calif.

CHARLES E. LYGHT, M.D.,* who has been Professor of Health and Physical Education and Director of Student Health Service at Carleton College, Northfield, Minn., has been appointed Director of Health Education of the National Tuberculosis Association in New York, succeeding H. E. KLEINSCHMIDT, M.D.,* who resigned last summer. Dr. Lyght is a graduate of Queens University Faculty of Medicine, Kingston, Ont. He served for 9 years on the faculty of the University of Wisconsin Medical School, being connected with the Department of Student Health. He has been Chairman of the Tuberculosis Committee of the American Student Health Association.

LENORE V. L. PATRICK, M.D.,† of Chipewewa Falls, Wis., formerly with the Wisconsin State Board of Health, has been appointed Chief of the Bureau of Maternal and Child Health of the West Virginia Department of Health.

HERBERT L. PETTITT, M.D., of Morrison, Ill., resigned on October 26 as Assistant Director of the Illinois State Department of Public Health to return to private practice, due, it was stated, to the shortage of physicians in his home city.

NORMAN S. REED, M.D., of Caldwell, Ohio, has been appointed Health Commissioner of Noble County, to succeed EDWARD G. DITCH, M.D., of Caldwell, who entered military service.

THURMAN B. RICE, M.D.,† Health Education Consultant, Indiana State

Board of Health, Indianapolis, has been appointed Acting State Health Commissioner. JOHN W. FERREE, M.D.,* of Indianapolis, has been granted leave of absence as State Health Commissioner, to serve as Lieutenant Commander in the Medical Corps of the U. S. Navy; Dr. Ferree has been State Health Commissioner since October, 1940, and had also served as Chief of the Bureau of Local Health Administration. Dr. Rice, until his recent appointment as Health Education Consultant, was Chief of the Bureau of Health and Physical Education.

RUSH R. RICHISON, M.D., has been appointed Health Commissioner of Springfield, Ohio. He was succeeded as Health Commissioner of Clark County by ROBERT M. TAYLOR, M.D., of North Hampton.

WILLARD J. STONE, M.D.,† of Corvallis, Ore., has been appointed Health Officer of Marion County, succeeding VERNON A. DOUGLAS, M.D.,† of Salem, who was on leave of absence for the Oregon Civilian Defense Council.

JAMES F. WILSON, M.D.,† of Washington Courthouse, Ohio, has resigned as Health Commissioner of Fayette County, a position he has held for 16 years.

Eastern States

MARY M. ATCHISON, M.D., M.P.H.,† of Concord, N. H., for some years Director of the Divisions of Maternal and Child Health and Crippled Children's Services and Acting Director of the Division of Epidemiology and Local Health Work, was recently named Acting Deputy Secretary of the New Hampshire State Board of Health. In her new position, Dr. Atchison will coöperate with local health authorities in the promotion of community health programs. MILDRED I. A. CHAMBER-

* Fellow A.P.H.A.

† Member A.P.H.A.

LIN, M.D., of Hillsboro, succeeded Dr. Atchison as Director of the Division of Maternal and Child Health and Crippled Children's Services.

CLEON W. COLBY, M.D., Health Officer of Exeter District, Exeter, N. H., has been named Acting Director of the Divisions of Epidemiology and Venereal Disease Control recently consolidated. For the present, Dr. Colby will continue in charge of the Exeter office.

BENJAMIN G. HORNING, M.D.,* Associate Field Director of the American Public Health Association since August 1, 1940, has resigned to accept the position of Field Director of the W. K. Kellogg Foundation. M. R. KINDE, M.D.,* who formerly held this position, received a new assignment as the Foundation Medical Director. Dr. Kinde is at present on leave of absence and is serving as a Major in the Medical Corps attached to the North Atlantic Division of the United States Army Engineers, New York, N. Y.

THEODORE E. HYNSON, M.D., M.P.H.,† formerly of Dover, Del., has been appointed Health Officer of Harlan County, Ky.

JACOB KATZEFF, M.D., formerly of Brooklyn, N. Y., has been appointed Health Officer of LaFourche and Assumption Parishes, Louisiana.

JOSEPH H. KINNAMAN, M.D., M.P.H.,* has resigned as Health Officer of New Rochelle, N. Y., to accept the position as Director of the Kay County Health Unit, Ponca City, Okla. Headquarters for the new Unit will be Ponca City and Blackwell. The new unit will consist, beside the Director, of an Assistant Director, HOSMER JOHNSON, M.D., 2 sanitarians, 2 clerks, an administrative

assistant, a supervisor and 6 staff public health nurses.

M. J. PLISHNER, M.P.H.,† formerly of the Tuberculosis and Health Association, Brooklyn, N. Y., now is a Captain in the Sanitary Corps, A.U.S., with a present assignment of Medical Inspector; Harbor Defenses of Chesapeake Bay and Fort Story, Va., with headquarters at the Station Hospital.

Southern States

JUANITA L. BOLTON, M.D., of Birmingham, Ala., has been appointed Health Officer of St. Clair County.

JAMES F. BRADLEY, M.D., of Liberty, Miss., has been appointed Health Officer of Noxubee County, succeeding GEORGE E. GIBBONS, M.D., of Macon.

PHILIP S. BROUGHTON,* who has recently served with the Social Security Board and formerly in connection with health education projects in the New York City Department of Health, has been appointed Director of the Division of Information, War Manpower Commission, Office of Emergency Management, Washington, D. C.

THOMAS BURK, M.D.,† of Rayville, La., has been appointed Health Officer of Copiah County, with offices in Hazlehurst, Miss., succeeding JOHN C. MCGUIRE, M.D.,† of Hazlehurst.

G. G. CAUGHMAN, PH.G., has been chosen Health Officer of Columbia, S. C.

FRANCIS H. COLE, M.D., of Nashville, Tenn., has been placed in charge of the Division of Tuberculosis Control of the Memphis and Shelby County Health Department, effective July 1. He succeeds FELIX A. HUGHES, JR., M.D., of Memphis, who has been assigned to take charge of Lynnhurst Sanatorium, Oakville.

JAMES J. CORBALIS, JR., B.C.E.,† resigned as Sanitation Officer with the Virginia State Health Department,

* Fellow A.P.H.A.

† Member A.P.H.A.

serving Fairfax County, Virginia, in the capacity of Sanitary Engineer, to accept a position with the county of Fairfax as Sanitary Engineer for the organization and administration of two sanitary districts within which water and sewerage works are now being provided by the Federal Works Agency and which constitute the Metropolitan Area of Fairfax County adjoining Arlington County and the District of Columbia with an estimated population of 40,000 people embracing an area of 31 square miles.

EUGENE H. COUNTISS, M.D., of New Orleans, La., has been named Chief of the Emergency Medical Service in Louisiana.

HUBERT D. CROW, M.D., has been appointed Director of a combined district health unit comprising the counties of Southampton, Isle of Wight, Nansemond, Va., and the city of Suffolk, with headquarters in Suffolk.

JAMES A. DOLCE, M.D.,† U. S. Public Health Service, Washington, D. C., has been appointed Health Officer of the Fairfax-Prince William-Stafford Health District, succeeding CLIFFORD E. WALLER, M.D.,* of Leesburg, Va., who remains as Health Officer of Loudoun County, with headquarters at Leesburg. Loudoun County was formerly a unit in the health district.

LLOYD M. FARNER, M.D., C.P.H.,† of Nashville, Tenn., U. S. Public Health Service, has been placed in charge of the new Industrial Hygiene Division of the Washington State Department of Health. Dr. Farner, who has been lent to the state by the Public Health Service, organized and served as Director of a similar division in Montana and later as Director of Industrial Hygiene in Tennessee.

OWEN A. GROVES, M.D., recently Health Officer for Kanawha County,

West Virginia, has been commissioned First Lieutenant in the Army Air Corps and left recently for the Army Training School at Miami Beach, Fla. No successor to Dr. Groves has been appointed.

JOHN H. HINES, M.D., of Canton, Miss., has resigned as Health Officer of Madison County, to join the Army.

HOWARD G. HOLLAND, M.D., of Leesburg, Fla., has been appointed medical consultant for the Florida Industrial Commission.

WILLIAM D. MAY, M.D.,† of Meridian, Miss., has been named Director of the Alcorn County Health Department, succeeding ROBERT H. DEJARNETTE, M.D.,† of Corinth, who has entered the Army.

MARVIN E. McRAE, M.D., of Chatham, Va., Health Officer of Pittsylvania County, succeeds SAMUEL S. SHOUSE, M.D., of Luray, Health Officer of the Page - Warren - Shenandoah Health District, who was granted a leave of absence to enter military service.

BRUCE H. POLLOCK, M.D.,* formerly the Director of County Health Work in the West Virginia State Department of Health, Charleston, is a Lieutenant Commander in the U. S. Navy and is stationed at Boston, Mass.

WILLIAM R. RICHARDS, M.D., formerly of Calhoun, Ga., has been named Health Commissioner of Green County, Greensboro, effective July 1.

J. E. ROBINS, JR., M.D., has been named City Health Commissioner of Charleston, W. Va., to succeed F. B. CARLSON, M.D., who resigned to enter the service as a Lieutenant in the Navy Medical Corps.

MARGARET M. SCANNELL, M.D., formerly of Meridian, Miss., has been named Medical Director of the Sunflower County Department of Health, succeeding ANDREW HEDMEG, M.D.,† of Indianola, who has entered the military service.

* Fellow A.P.H.A.

† Member A.P.H.A.

MARTIN H. SKAGGS, M.D., of Taylorsville, Ky., was recently elected Health Officer of Shelby County.

DANIEL C. STEELSMITH, M.D., has been named to take charge of the newly consolidated Halifax-Pittsylvania Health District (Halifax and Pittsylvania Counties), with headquarters at South Boston, Va.

RAYMOND D. TOMPKINS, M.D., of Mountain Home, Tenn., has been appointed Chief Medical Officer at the U. S. Veterans Administration Facility, Bay Pines.

EDGAR W. WARREN, M.D., of Abbeville, La., Director of the Vermilion Parish Health Unit, has been appointed to a similar position in Jefferson Parish.

GORDON R. WESTROPE, M.D., Director of the Cherokee County Health Department, Gaffney, S. C., has been appointed Director of District No. 2, including 11 upper state counties.

Western States

CHARLES BENNINGER, JR., M.D., City Health Officer of Oroville, Calif., has been appointed County Health Officer of Butte County, to succeed LOUIS C. OLKER, M.D., of Chico, who resigned.

PAUL G. BUSS, M.D., of Los Angeles, Calif., has been appointed Assistant County Health Officer of Orange County, Anaheim.

HERALD R. COX, Sc.D., Chief Bacteriologist at the Rocky Mountain Laboratory, U. S. Public Health Service, Hamilton, Mont., and President of the Montana State Public Health Association, has accepted a position as Associate Director of Research for the Lederle Laboratories, Pearl River, N. Y. He will have charge of all virus disease work.

WILLIAM P. FRANK, M.D.,† of Alhambra, Calif., has been appointed

Health Officer of the Alhambra District, including El Monte, Monterey Park, San Gabriel, San Marino, and South Pasadena.

JOHN A. KAHL, M.D., M.P.H.,† of Walla Walla, Wash., has been appointed to take charge of the newly combined tri-county health district, comprising Walla Walla, Franklin, and Benton Counties.

HAROLD L. LAWRENCE, M.D., of Seattle, Wash., Passed Assistant Surgeon of the U. S. Public Health Service, has been appointed Chief of the Division of Epidemiology and Venereal Disease Control of the Washington State Department of Health, Seattle.

ARTHUR E. LEWIS, M.D., U. S. Public Health Service Reserve, has been assigned to Seattle, Wash., as Assistant State Medical Officer for Civilian Defense.

ROSCOE C. MAIN, M.D.,* of Los Angeles, Calif., formerly Health Officer of Santa Barbara County, has been appointed in charge of the Glendale District Health Unit, succeeding JOHN M. BUCHANAN, M.D., of Glendale, who has entered Army service.

DOROTHY Z. E. McDONALD, M.D., C.P.H.,† of Madison, Wis., Advisory Physician in School Health Education of the Bureau of Maternal and Child Health of the Wisconsin State Board of Health, has resigned to become Vice-Chairman of the Department of Public Health of Loyola University Medical School, Chicago, Ill.

LESTER S. McLEAN, M.D., of San Francisco, Calif., was named Health Officer of Solano County, August 3, succeeding GEORGE O'BRIEN, M.D., of Fairfield, resigned.

CEDRIC NORTHROP, M.D.,† a member of the Washington State Department of Health, Seattle, since December, 1941, has been appointed Chief of the Division of Tuberculosis Control.

* Fellow A.P.H.A.

† Member A.P.H.A.

CHARLES EDWARD SMITH, M.D., D.P.H.,* has been promoted to a full professorship in public health and preventive medicine at Stanford University, San Francisco, Calif.

DEATHS

CHARLES RALPH ARMSTRONG, for 30 years Superintendent of the Trudeau Sanatorium, Trudeau, N. Y., died November 9, at the age of 71.

HOWARD B. METTEL, M.D.,* of St. Louis, Mo., died recently. He was Chairman of the Maternal and Child

Health Section of the American Public Health Association.

LEROY A. WILKES, M.D.,* of Trenton, N. J., died November 29, at the age of 59. He was Executive Officer of the Medical Society of New Jersey, and former Medical Director of the Austrian child health program of the Commonwealth Fund of New York. Dr. Wilkes was a Fellow of the American Public Health Association, and served as Chairman of the Child Hygiene Section 1931-1933, Vice-Chairman in 1934, and Chairman again in 1935.

* Fellow A.P.H.A.

CONFERENCES AND DATES

American Academy of Orthopaedic Surgeons. Chicago, Ill. January 17-21.

American Association of School Administrators. St. Louis, Mo. February 26-March 2.

American Society of Civil Engineers—Winter Meeting. New York, N. Y. January 19-22.

Annual Forum on Allergy. Cleveland, Ohio. January 9-10.

American Water Works Association—Canadian Section—Royal Connaught Hotel, Hamilton, Ontario, Can. April 7-9.

Pacific Northwest Section—Bellingham, Wash. May 7-8.

Conference on War Winning Water Works Operations—June 14-17. Carter and

Statler Hotels (co-headquarters), Cleveland, Ohio.

Clinical Orthopaedic Society. Chicago, Ill. January 18-21.

Fifth Annual Congress on Industrial Health—sponsored by the Council on Industrial Health of the American Medical Association. Palmer House, Chicago, Ill. January 11-13.

National Conference of Social Work. Cleveland, Ohio. May 23-29.

Rocky Mountain Medical Conference. Biennial Conference. Albuquerque, N. M. May 18-20.

Social Hygiene Day—American Social Hygiene Association. February 3.

The Present Epidemiological Basis of Environmental Sanitation*

GAYLORD W. ANDERSON, M.D., DR.P.H., F.A.P.H.A.†

Professor and Head of the Department of Preventive Medicine and Public Health, University of Minnesota, Minneapolis, Minn.

ENVIRONMENTAL sanitation is the oldest form of public health endeavor. To it can be attributed the reduction in cholera and typhoid fever, much of the reduction in summer diarrheas, control of many of the milk- and food-borne infections, elimination of yellow fever from certain areas, progress in malaria control, forward steps in elimination of industrial hazards—in short, some of the outstanding accomplishments of public health workers.

That sanitation should be the foundation upon which the modern superstructure of public health has been erected was the inevitable result of the evolution of concepts of infectious disease. As our predecessors conceived these to be due to inhalation of toxic emanations from decaying filth, early public health attention was logically directed at cleanliness of the environ-

ment. The advent of the era of bacteriology made possible the separation of the program into two components, the one with a specific disease prevention value, the other with mere esthetic value. It was thus possible to concentrate on those aspects that had health significance, rather than dissipate energies in attempts to attain mere cleanliness.

Although this concentration was desirable, it had, nonetheless, an unfortunate consequence for it led to a tendency to reject all measures that could not be shown to have specific value in disease prevention. "Clean dirt" was distinguished from "dirty dirt," and municipal sanitation was divorced from public health engineering. The sanitation program was reduced to what was often called "its bare essentials," and a notable local health demonstration was even begun without provision for sanitation.

Although I am in hearty accord with attempts to eliminate useless procedures, such as some of our ridiculous and almost barbaric quarantine requirements,

* Presented at a Joint Session of the Engineering and Health Officers Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

† Now Major, Medical Corps, Army of the United States

I nonetheless submit that complete disregard of the esthetic aspects of environmental sanitation is not only illogical but even detrimental to public health progress. Many of these esthetic components have contributed immeasurably to our standard of living. The cleanliness of a community's streets, parks, food handling establishments and public buildings, including the public toilets, is a true measure of its standard of living. If we neglect these, we sink into a neglect of measures of greater importance. The standard of living is a vital factor in community health, important in the decline of many diseases, notably tuberculosis and infant diarrheas. I do not wish to belabor the point, nor have I time to be more specific. I do, however, wish to emphasize that in attempting to place environmental sanitation on a sound epidemiological basis we must not so completely lose sight of the intangible esthetic aspects that what we today consider progress through elimination of nonessentials is revealed tomorrow as a backward step.

Without losing sight of these esthetic elements, let us examine some of the present epidemiological bases for environmental sanitation. Since the recent issues of our JOURNAL suggest that there may be many shades of meaning applied to the term "epidemiological," I must define the limits of the term for this discussion. I conceive of epidemiology as the science of the occurrence of disease. It embraces consideration of all factors bearing on the development and prevalence of any disease condition. We must, therefore, examine the extent to which disease in the individual or the community may be influenced by the environment. Entire volumes have been written on only small parts of this broad topic. Here I may direct attention to only a few salient points.

Improvement in water supplies needs

no justification. There is ample evidence of the relationship between specific contamination and intestinal infection. It may not be out of place, however, to point out the danger that our past triumphs may engender a smug complacency that will be periodically shaken by the recurrence of disease. We are constantly being treated to the unpleasant spectacle of a public using with apparent impunity water that does not conform to accepted standards. There is danger that some of us may conclude that the standards are unnecessarily strict and not justified by current epidemiological experience.

To do so would be to display a fundamental lack of insight into the basis of these standards. Based on extensive experience showing that water with a certain degree of pollution cannot be drunk without risk of contracting typhoid fever, they presuppose a numerical relationship between the number of typhoid and colon bacilli in the sewage of a community. That this ratio is not the same for all communities or for long periods of time in the same community is well known to the epidemiologist. The community that has had much typhoid fever in the past 20-30 years has a higher ratio of typhoid to colon bacilli than has the community with a low typhoid record. It is not surprising, therefore, that the latter may use with impunity a water with a colon index that would be positively dangerous for the former. This does not mean that the standard is wrong but rather that the community is flirting with danger of future trouble if it disregards the obvious implications of the standard. The possible appearance of dysenteric infections if the standard be disregarded is also a threat that cannot be ignored. If we attach the least degree of esthetic significance to the drinking of water containing the living excreta of another man's bowel, the standard is also good.

The possible rôle of water in the development of other diseases is important to the engineer and epidemiologist alike. Discovery of the virus of poliomyelitis in the excreta of patients and carriers, and in the sewage of a community in which the disease is prevalent, naturally raises the suggestion that the disease is water-borne, and that added attention may have to be given to purification of water and disposal of sewage.

It should be pointed out, however, that the mere presence of micro-organisms in feces does not mean that the normal mode of spread is via water to which sewage finds access. The organisms of tuberculosis and pneumonia may be found in feces and yet there is no evidence that either disease is spread by water that we drink or in which we swim.

Before we can assume the spread of poliomyelitis through water, we must show the occurrence of the disease to be consistent with such a hypothesis. It is to be regretted that too little attention has been paid to the wave-like character of spread, a phenomenon pointed out so clearly by the late Dr. Wade H. Frost as long ago as 1916. One cannot accept the concept of spread through water when he sees the disease spreading (like measles) as ripples spread from a stone dropped in a quiet millpond, the peak of incidence in contiguous geographical areas of a single city showing a regular progression from a focus—all this in an area with a single water supply. Personally I am aware of no outbreak of poliomyelitis in which the epidemiological evidence even suggests water as a vector to the exclusion of other channels of infection; on the other hand, I am familiar with innumerable outbreaks in which the water-borne hypothesis is absolutely untenable.

If on epidemiological grounds I would exclude poliomyelitis from the possible

sphere of sanitary control, by the same token I would direct your attention to the possible rôle of environmental regulation as an element in the fight on dental caries. Although caries is obviously the result of the interplay of many forces, the metabolism of fluorine seems established as a factor of importance. The work of numerous investigators indicates a higher incidence of caries in a community drinking a fluorine-free or deficient water than in one using a water that will induce a low degree of fluorosis. Brekhuis and Armstrong have found the fluorine content of the carious tooth lower than that of the non-carious. Only a few years ago fluorine was enthusiastically removed from water to prevent mottling of the teeth. Today we must consider the possibility of adjusting the content to a level that may inhibit development of caries and yet not induce fluorosis. Although much remains to be learned before the method is practical, I feel confident that the day is coming when fluorine may be added to some waters and subtracted from others with resultant benefit to dental health.

In the realm of milk sanitation, modern epidemiological concepts also support the basic tenets upon which our program is based. Unfortunately, however, much of our milk sanitation antedates careful studies of the "sources and modes of infection." It is not surprising, therefore, that many milk codes should contain items that are not easily justified. They may be defended on the ground that they conduce to a low bacterial count, yet the emphasis that is placed on nonessentials is too often at the expense of items of far greater importance. I refer to some of our haggling over barn design or location of manure piles to the disregard in many communities of an obvious need for pasteurization.

In a recent issue of *Harpers* a former Department of Agriculture employee

charges that some of the high price of milk is due to unnecessary sanitation: "For more than eighteen years the U. S. Public Health Service has been urging the universal adoption of uniform, sensible milk standards, but less than one-third of the nation's milk areas have thus far fallen in line." Had the author been less concerned with accusation, he would have had to add that a substantial part of the recalcitrant two-thirds has standards so far below those of the U. S. Public Health Service Standard Milk Ordinance that, in the words of one of our late associates "anything can be sold as milk that is white, pours and comes from a cow." To present the complete picture he would have also had to add that in at least one state the agricultural interests, in spite of health department opposition, forced adoption of grading legislation that precluded adoption of the standard milk ordinance. It is unfortunate that popular magazines should peddle half-truths to a gullible public.

Yet in the writer's charges there is nonetheless some element of justice. Overlapping inspection and too zealous exercise of local prerogatives often result in needless expense to the farmer without sanitary justification. It behooves us to appraise our milk regulations from time to time, not solely to make them more stringent but to determine if they rest on a firm epidemiological basis. I feel confident that most of them will stand the searching light of scrutiny but there are some that I know will not. Merely as examples of the latter I would cite regulations as to collection of milk bottles from homes with communicable disease and the sale of milk from farms where infection exists.

I recall visiting a home in which four cases of meningococcus infection had occurred over a period of as many months. As the house had been under

constant quarantine, the milk bottles had so accumulated that they covered a large front porch except for a narrow path to the door. It was through this path that I walked with my portable incubator to carry throat cultures to the laboratory. I had to transport them in the incubator lest the organisms die in the March cold; yet apparently the board of health considered that they might live for weeks or months on dry milk bottles which were being accumulated for a final orgy of disinfection. If the usual cleansing methods are inadequate to treat bottles from the home where frank cases exist they are equally inadequate for those from homes harboring the more numerous carriers and missed cases. Either the measures are shockingly inadequate or these special precautions are unreasonable.

Somewhat similar considerations apply to measures of dealing with milk from infected farms. All too commonly this is excluded from even the pasteurization plant. I do not for a moment question the importance of excluding this milk from sale if it is to be distributed raw. In the case of a pasteurized supply the case seems to me to be different. I recently found considerable horror expressed over the practice of one state of permitting creameries to accept milk from farms where typhoid fever carriers reside. Yet I submit that if the process of pasteurization is inadequate to kill typhoid organisms where they are known to exist and suitable precautions taken to guard against their introduction into the milk, the same process is equally inadequate to destroy those that enter from unrecognized carriers. Epidemiological experience shows the process to be adequate. Nor do I know of any evidence that this more lenient point of view has resulted in disease—unless perhaps a phobia on the part of its critics.

In the field of food sanitation we also find practices that do not rest on sound epidemiological basis. At the risk of possible misinterpretation I must emphasize what should by now be a truism, that mere spoilage of food does not render it unfit for human consumption. The fondness of the sportsman for high game and of the epicure for certain cheeses belies the old presumption that protein decomposition products are poisonous. Personally I do not like my protein decomposed—beyond a certain point—and therefore welcome a food inspection that protects from the unscrupulous merchant who would attempt to defraud. We must, however, recognize this as fraud prevention, not as disease prevention. As fraud prevention it needs no apology; masquerading as disease prevention it stretches intellectual honesty to the breaking point.

I wish I could cite evidence that lack of decent cleanliness in the handling of dishes in food handling establishments is likely to result in demonstrable disease, for I should welcome a basis for enforcing better dishwashing in the restaurant and soda fountain. And yet I know of no convincing evidence of this character. This does not mean that we should relax in our efforts to achieve decent standards of cleanliness—standards that satisfy our better esthetic senses, bespeak a high standard of community cleanliness, and assure destruction of the pathogens likely to be spread through the mouth. It is better to seek these standards than to dissipate our efforts in attempting to achieve bacteriological sterility with complicated devices of more value to the manufacturer than to the public. In our hospitals we are even more illogical in that we often insist that dishes of the infectious patient be boiled for ten minutes. Can it be that when we increase the temperature from the 160° F. that is effective in the

short-time, high-temperature pasteurization to the 212° F. of boiling we must increase the time from 20 seconds to 10 minutes? Or can it be that measures adequate for the dishes soiled by the unrecognized carrier are inadequate for those used by the recognized case?

The problem of waste disposal, and particularly contamination of bathing places, offers another situation in which we must fall back upon esthetics for support of current practices. I am not condoning dirty, filthy, or polluted swimming pools or beaches. We have a right to demand that the water in which we bathe is not mere diluted sewage. Common decency dictates cleanliness and needs no apology. Yet in setting up these standards we must not delude ourselves into believing that we will materially affect the incidence of communicable disease. I have heard many accusations as to the spread of disease through swimming, yet for none of these can I find evidence that is even presumptive. Respiratory diseases have been spread at beaches and pools, yet I see no evidence that this has been through water rather than direct respiratory exchange. Skin infections may well be spread through exchange of towels and bathing suits and conceivably by lying on a moist sandy spot recently vacated by a sufferer from such infection. I would not deny this possibility or even probability, but no one has suggested disinfection of the sand though many have urged disinfection of the water to prevent spread of impetigo. Some have even suggested that venereal diseases might be spread through the waters of bathing beaches. I would not deny that these diseases have been spread at the beaches but I insist that it is not through the medium of water. Sanitation of swimming pools and beaches is a matter of such obvious common decency that it needs no support from far-fetched

epidemiology. Unfortunately epidemiological experience cannot even assist in the determination of reasonable standards.

Industrial hygiene has probably made more progress than any other branch of environmental sanitation in its attempt to base control practices on a sound epidemiological foundation. Tolerances for specific chemicals have served as the basis for standards of concentrations to be permitted in the working environment. The fact that a dust-free or fume-free atmosphere was neither attainable nor essential has been faced realistically and control efforts directed at reducing concentrations below the critical levels determined by experience.

This is a refreshing contrast to the attitude too often displayed in certain other phases of public health control. The attitude to which I refer is that of sitting with the feet before the fire, some mental stimulant at the elbow, and thinking up regulations to control every conceivable hazard to which man may be exposed. Of course, it will be objected that the chance acquisition of a small dose of bacteria is of vastly more significance than of chemicals because of the former's capacity for reproduction. Yet as already pointed out the mere demonstration of the presence of bacteria in the environment does not imply epidemiological significance. Due consideration must be given to the problem of dosage and the capacity to infect when introduced by various portals of entry. We could profitably emulate our brothers in industrial hygiene and attempt to put some of our other control measures on a sound basis of experience rather than on mere theory.

Of the many newer aspects of environmental sanitation, the standards of housing seem to rest on especially insecure epidemiological foundation. I would not question the potential health

significance of housing, and yet epidemiological data on which to base this belief are virtually nonexistent for poor housing cannot be separated from other attributes of poverty.

This inability to secure epidemiological support for housing standards should not discourage us from attempts to improve housing conditions or even to do so by regulation. Almost every community has houses that by no stretch of the imagination can be defended as desirable for human habitation. An appreciable fraction of our population lives under conditions that are undesirable socially, morally, and hygienically. Housing needs no defense nor need it await epidemiological support. It is important, however, that in our eagerness to effect improvements through use of regulatory power, we do not deceive ourselves as to the limitations of our knowledge. We must keep an open mind and be prepared to modify our standards in the light of future research; not attempt to defend the unreasonable on the basis solely that it is hallowed by tradition.

In presenting this brief discussion of the present epidemiological basis of environmental sanitation, I have purposely sought to avoid philosophical discussion of general principles. Rather have I sought to cite a few examples, chosen at random from varying fields, to illustrate the extent to which current practice may or may not rest on a sound epidemiological foundation. From your own experience you can each add countless examples. You can draw from fields that I have not attempted to touch, such as insect control. You can generalize far more than I have attempted to do. You will find, as I have already suggested, that on the one hand we have sought to base standards on epidemiological evidence that does not exist and on the other hand have ignored well established evidence. In short, we have been supremely human.

In acknowledging the lack of epidemiological support for many of our sanitary practices, I trust that I shall not be branded as an iconoclast, as I was so labelled in jest by one of your members a year ago. It would be Utopian if we could find sound basis for all measures of sanitation, but at present we cannot and I doubt if we ever shall. This lack need not deter us, however, from attempts to improve the sanitary standard of the community.

Cleanliness is still next to Godliness and will always remain so. It needs no apology. It is essential, however, that we maintain a clear perspective if we are to preserve our intellectual honesty. This perspective requires periodic re-evaluation of our practices, elimination of the illogical and unnecessary without undue sacrifice of those esthetic components that conduce to that intangible yet highly valuable asset that we refer to as the standard of living.

Science and Government

A PRESIDENT may use the findings of scientific agencies in a truly scientific way—for the purpose of developing the soundest possible national policies. Or he may use these resources for the purpose of support for policies which have been predetermined by political considerations. As the primary seat of power, the President is in a position to exert pressure throughout the administrative personnel of the government. The scientific personnel in government departments may assemble the data required with true

scientific objectivity; but they are usually debarred from interpreting the meaning of the data or formulating conclusions to be drawn therefrom. This, as previously indicated, is the function of the bureau chief who is nearly always a part of the political hierarchy. In short, scientific men can be scientific up to a point; and the point beyond which they cannot go is usually the vitally important point. Quotation from article by Dr. Harold G. Moulton, "Science and Government," in *Science*, Dec. 11, 1942.

A Physician Looks at School Dental Programs*

GEORGE M. WHEATLEY, M.P.H., M.D., F.A.P.H.A.

*Assistant Medical Director, Metropolitan Life Insurance Company,
New York, N. Y.*

MY purpose in this paper is to look back several years at our experience with developing an economical dental program in the Astoria School Health Study. In these days of civilian economy and rationing, procedures which bring results without increasing costs are, I believe, worth review. The full description of the dental program upon which my remarks are based is given in the published report of the Astoria Study titled "Solving School Health Problems,"¹ and also in several papers by Lifson.²

I make no claim that this program is unique. It is similar to one Turner³ has successfully conducted in Malden for many years. I am encouraged to discuss it because now it may have more significance, since it has the virtue of being economical. I have not tried, even if it were possible, to evaluate this program by any of the criteria recently suggested by Knutson⁴ in his constructive paper in the *Public Health Reports*, nor can the results be accurately measured as Kramer⁵ has been able to do for his state-wide activities in Kansas. Most of the data are limited to one year's experience. They are based for the most part on examination and treatment by private dentists who, as you all

understand, vary in their standards of work.

Nevertheless, I believe the experience deserves reviewing because it faced some very fundamental questions. They are questions which every public health dentist and school health administrator ponders: How can I develop an effective program without increasing the budget? How can I utilize the dentists of the community in the school dental program? How can I make the most effective use of a dental hygienist? What responsibility can the elementary school classroom teacher assume in dental follow-up? Is the school the place for the dental examination? From this experience, we found that the private dentist can and should have a more intimate working relationship with the school dental program; that elementary school classroom teachers were not as effective in securing dental attention for children in the primary grades as in the upper grades; that the dental examination does not belong in the school but in a dentist's office; that this program can operate without additional funds, when more effective use of existing school and community resources is made.

A DESCRIPTION OF THE PLAN

The operation of this dental program involves principally the teacher and the community dentists, with the school nurse playing a secondary rôle. The teacher has three responsibilities: (1)

* Presented at a Joint Session of the American School Health Association, and the Oral Health Group of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

To inform all parents once each year that the child needs a dental examination; (2) To conduct systematic contacts with the home until the child receives attention; (3) To record on each child's *Pupil Health Card* the progress he has made during the school term in obtaining treatment.

The private dentists agree to give a dental examination to any child coming to their offices accompanied by a parent. The nurse's responsibility is to make a limited number of appointments in the school dental clinics and other available clinics for those children obviously clinic cases or who are recommended for clinic care by private dentists. It will be shown below that the plan would have been more effective if, for the primary grades, our procedures included a personal interview by the teacher or school nurse with the parents of those primary graders who do not respond to the teacher's letter urging a dental examination.

Four steps were necessary to initiate the program. Fortunately, at this time the two dental members of the District Health Officer's Medical Advisory Committee were the presidents of the two dental societies in the community. First, the program was explained by the District Health Officer to these two dentists. Second, these dentists called a meeting of all dentists serving the Astoria-Long Island City Health District and discussed it in open meeting. Third, after the coöperation of the community dentists was assured, the plan was proposed first to the district superintendent of schools and then to the eight school principals concerned. Fourth, a letter to be sent to each parent was formulated by the Study Staff and submitted to representatives of the dental profession and school authorities for approval. This letter carried the signature of the principal of the school attended by the child.

RESULTS

What were the results? At the end of the school year, 1937-1938, for which we have complete data, 88 per cent of the children in the eight schools participating in the demonstration had been examined by dentists. Private dentists examined two-thirds of the school registrations; supplied almost three-quarters of the treatment services; and were responsible for 82 per cent of the cases completing treatment. Treatment was found unnecessary for 21 per cent of the children examined. Parents of 1,859 of the children took no action. This is 29 per cent of all the children in the group. This figure includes 17 per cent found by a dental examination to need treatment but who did nothing about it, and 12 per cent who never availed themselves of the examination. An inquiry was made as to why parents did not take their children for dental examination or secure necessary treatment. About one-half the responses were classified as indicating lack of understanding or unwillingness to coöperate. The other large group were those whose excuse was economic need.

THE RÔLES OF THE TEACHER AND DENTAL HYGIENIST

When the results were analyzed by grades, we discovered that the lower the grade, the less dental care the children received. For example, 44 per cent of the children in the kindergarten never reached the dentist even to be examined. On the other hand, above the 4th grade 90 per cent or more in each grade visited a dentist. Thus, in the age group for whom protective dentistry is most important, the teachers' efforts were least successful. While these poor results may be explained by lack of appreciation by the teachers of the importance of early care of baby teeth and 6 year molars, it is likely that the parent influences the situation more in this younger group than in older chil-

dren. If parents do not believe that care of baby teeth is important, the primary school child is not likely to be taken to the dentist, regardless of the notes he may bring home from the school recommending a visit to the dentist.

This assumption is strengthened by two other studies made in Astoria in which the dental hygienist's efforts were compared with those of the teacher. A dental hygienist worked with 238 children in the 7th grade. Her procedure was to send a note to the parent and, if no visit was made to the dentist, to have one or two conferences with the child. Of all the children who received care by this plan, 90 per cent obtained it within 6 weeks after the dental hygienist's first note sent to the parent. Completed care was obtained for about 30 per cent of the children. Nearly 30 per cent of the children received no dental care in spite of the repeated efforts of the dental hygienist. On the other hand, we have already observed that teachers were much more successful with this upper grade group. A study made by Frankel,⁶ using four schools in Astoria, supports the theory that the parent is the important factor in securing dental care for primary graders. Using schools which children of relatively the same economic status attended and using 1st, 3rd, and 4th grades, the children were examined by a dentist who determined the condition of their teeth at the beginning of the experiment and reexamined them at the end of the 7 month period of the study. In three of the schools the teachers did the same follow-up work as has just been outlined. In the fourth school, a dental hygienist was used to interview the parents of those children who did nothing after the first note was sent home. It was found that, in terms of dental correction secured, the children where the dental hygienist worked with parents had received almost three times more

dental care at the end of the 7 month period than the children in the schools where notes alone were employed.

I do not believe this conference method depends for its success entirely upon a dental hygienist. Any school health worker such as school nurse, physician, or teacher, who can meet the parent and discuss intelligently the value of dental care and demonstrate to the parent any obvious caries that need attention probably will be equally effective with this younger group. The result obtained by the teachers in the upper grades is, for practical purposes, quite satisfactory and indicates that for this age group the individual conference method is not essential to secure dental care for most of the children. This difference in the method of follow-up which must be employed, depending upon the age group of the children, is worth noting because today in the interests of economy and more effective use of limited professional personnel in the school program we need to know more than ever before where professional services must be applied to bring the greatest return.

SHOULD THE DENTAL EXAMINATION BE MADE IN THE SCHOOL?

The purpose of a school dental examination is to detect dental defects early so that prompt correction is possible. Yet reports indicate that dental caries is present in 80 to 90 per cent of all children.⁷ It hardly seems like economical public health practice to spend time, which is money, in the examination of hundreds of children in order to single out the small group of children with sound teeth, and these teeth might not be free from caries if x-rays were taken. If this examination were to be made in a dentist's office, which is the usual place for treatment, it would be of greater educational value. The school's job regarding dental health is to educate every child in proper dental practices.

Is the school fulfilling this function effectively when it teaches children to depend upon the school for dental service, knowing that this paternalism will end at graduation? It would appear to be better policy for youth to learn while it is still in school the path to treatment facilities in the community. Youth should also learn that dental fillings are worth paying for.

In defense of the dental examination in the school it is admitted that it may identify the serious cases which need attention sooner than others. It is said that these are the very cases which are most likely to ignore the advice of the school if all it does is urge a visit to the dentist to be examined. Again it probably comes down to a question of what is available in the budget and what policy is likely to result in the greatest good for the greatest number.

THE PRIVATE DENTIST'S PART

As soon as one thinks of the private dentist being brought into more active participation in the school dental program, he thinks of all the reasons for excluding him. These are the same objections which many school medical administrators voice regarding the participation of the private physician. Prominent among the reasons are: (1) The great variation among private physicians in examining technic; and (2) lack of interest in children's health problems; (3) poor coöperation with the school; (4) inadequate record keeping. These are not insurmountable. Morris⁸ has answered these objections in his work with organized dentists in Michigan. We saw the solution as soon as we brought the Astoria dentists together to discuss the program.

It was during the first open meeting, I remember, when the dentists discovered and discussed their differences in examining technics. The dentists who used bite wing x-rays strongly urged that procedure be used by all. There

were many dentists who believed that the explorer was adequate. This is a technical problem which the Study considered had to be solved by the dentists. But it illustrates the opportunity for "painless" professional self education which a plan of this type offers. Along this same line were problems of standardization of the examination with respect to reporting of defects and the keeping of uniform records. There were some dentists, after a few months' operation of the program, who felt that the examining job should be carried out by a select few from the dental society members and that the examinations might be made in school. Before the program had been under way very long, some of the dentists complained of overcrowding their offices; others, who were located in the poorer sections of the district, got very few pay patients out of the examination program. There were, at the end of the year, many who reported that they had received many new patients through this program. Another interesting observation was that the private dentist completed treatment much more promptly than the clinic dentist. Actually, of all the children who completed treatment during the year, 82 per cent were finished by private dentists.

These developments are symptoms and signs of the learning process. Our plan had deficiencies, but the most important thing, to my mind, is that we succeeded in getting the dentists interested and participating. The slow process, the mistakes, the bickerings, all are healthy and necessary stages in the education of any body of private practitioners entering upon a group project.

In school health work the private practitioner can, in most communities, participate in the program more than he does. Even in communities where school dental clinics are highly organized, service is rendered to only a fraction of the children. And the need for service is

very great. McCall finds that many children have one or more decayed teeth at 2 or 3 years of age. Klein and Palmer show that the permanent teeth of children under 14 years of age are decaying as fast or faster than they are being filled.⁷ Eight out of ten N.Y.A. youths were found to have untreated dental caries.⁹ While some proportion of these children are in families who cannot pay anything for dental care, the per cent is not as large as some would have us think. Many children included in the data just cited are in families who can afford dental care, while in their community are dentists who are not busy. I think the basic problem is one of maldistribution. On this point Sandler¹⁰ says, "Only a small percentage of the children who can afford dental service actually receive it and there are few dentists who do not waste many precious hours waiting for patients." East¹¹ has found that non-relief families spend about \$9 a year for dental care, although they spend \$24 for tobacco. More than half the families of the United States, not including those on relief, spend nothing for dental care. Certainly with the national income breaking all records in most communities today there should be but few families who cannot afford expenditures for protective dental care if they believe in it.

From our experience not only in Astoria with school children, but in the Metropolitan Life Insurance Company with 15,000 clerical workers in the New York Home Office, much can be done to increase dental service by educational means. The Dental Division of the company reports that company employees receive almost twice as much dental care as the people in the highest income, studied a few years ago by the Committee on the Cost of Medical Care.¹² Dr. Dunning, Director of the Dental Division, says that this is due not to any higher cavity rate among

Metropolitan employees but is genuine evidence that individuals can and will afford a larger proportion of dental service under stimulation than they would be likely to think they could afford without such stimulation. Morris¹³ says that the relationship between the economic status and the willingness of the family to pay for the treatment is not as close as we generally believe. He says the Kellogg experience in Michigan has demonstrated that it is first necessary to educate the family as to the value of dental service, and at the same time to educate them that it is a service they should pay for. He adds also that they have not observed any tendency for families to relinquish the responsibility for payment as the child gets older. He goes on to say that last year economic conditions in the areas where the Kellogg program functions have been a great deal better than they have at any time since the program was initiated. The reports this year, he says, will show a tremendous increase in the number of private patients.

We shall achieve the goal of protective dentistry and preventive medicine when the individual practitioner understands these objectives. The protective dentistry and preventive medicine of a community is only as good as the work of the private practitioners in the community. We, public health physicians and dentists, must bear in mind that the private practitioner is the man who must apply our theory to the individual. Our ideals of early protection and correction of defects and regular health supervision are so many words unless the individual practitioner who sees the public, too late many times, both in dentistry and in medicine, understands these concepts. The best way for him to understand is through active participation in programs which are based on these ideas.

To interest the professional man in the health program, he first must be-

come aware of the significance of the problem in his own community, and then be willing to spend time and effort to analyze the problem and participate in trying to solve it. Those of us in public health have a responsibility to encourage our colleagues in private practice to participate in community activities. The average practitioner of medicine and of dentistry has not been taught as a part of his professional training how to join hands for a common objective. The nature of his work and of his income makes him an individualist. This is particularly true of the dentist. He is too occupied, and necessarily so, to take the initiative in such community projects. This deprives him of experience which he should acquire in order both to adjust to new circumstances, and to have a hand in shaping his own destiny as well as that of his profession. The approach to the dentist or physician is through his society. The better organized the society, the more likely is the prospect of developing interest and action.

I think public health dentists have made notable progress in this respect. For example, in the seven counties in Michigan where the Kellogg Foundation, under the direction of a dentist, has been financing community health service through county health departments, dental and medical service for school children is conducted entirely by the local practitioners.¹⁴ While this is probably slower as a method of securing a uniform high quality of work from the participants, nevertheless it seems to me far superior as a long-range objective than the introduction of clinic services which compete with the private practitioner and aggravate this problem of distribution and delay the day when all private practitioners will practise prevention as well as cure.

The dentists in Astoria are no different from professional men anywhere in this country. Many were suspicious of

the plan, seeing it "State dentistry." Some saw the variation in the quality of examination and treatment which would be given by different dentists. Others thought the Health Department should pay the private dentists for the service, and other proposals were made at the meetings when we discussed the plan with the community dentists. The fact that 17 per cent of the children who were examined did not return for treatment can be laid at the door of the examining dentist. But these are not irreparable faults: they are a challenge to our leadership. Morris,⁸ directing the Kellogg Foundation activities with private dentists in Michigan has used these as teaching opportunities. The dentists through their own organization can correct these deficiencies.

No claim of perfection is advanced to describe this Astoria program. It did place many children under dental care; it gave the teachers a concrete objective in their health teaching; it indicated that, in order to secure dental care for the younger age groups, individual conferences with parents are more necessary than with older children. It tended to distribute more efficiently the limited clinic services available in the district; it permitted a large number of practising dentists to participate for the first time in a public health effort, and most of them increased their clientele.

It is possible that in the future other solutions of this problem will come through the development of insurance schemes. Several have been suggested, but none, to my knowledge, are in actual operation. One of the factors which seems to operate against the development of dental insurance is that dental needs are too predictable on the part of the individual policy holder. There is practically no expectation of a cataclysm in the dental field such as medical patients might be willing to anticipate by the payment of premiums throughout long periods of good health.

Except perhaps in those communities where war industry has overwhelmed all available dental facilities, we cannot think today of expanding clinic facilities. We must aim toward using the already available dental man power and equipment 100 per cent of the time. The first step in that direction is to bring the private dentist into more active participation. We must avoid any duplicating or competing effort. By virtue of its educational functions and the population group it serves, the school health program exerts a strong influence on the entire health program. Wise leadership will promote the use of already existing facilities for protection and preventive health services. If services must be supplied by the school, it should not become a competitor of the community dentist, but supplement gaps he cannot fill. Too readily administrators accept the idea of a deficiency without being resourceful. As in many commodities today, a real shortage may not exist but be based on faulty distribution. Officials whose job it is to break these bottlenecks and improve this distribution problem are called "expeditors." We need more "expeditors" in our public health program.

Salmonella Typing in a Public Health Laboratory*

EARLE K. BORMAN, KENNETH M. WHEELER, PH.D.,
D. EVELYN WEST, F.A.P.H.A., AND FRIEND LEE
MICKLE, Sc.D., F.A.P.H.A.

*Assistant Director, Research Microbiologist, Chief Microbiologist, and Director,
Bureau of Laboratories, Connecticut State Department of Health,
Hartford, Conn.*

THE salmonelloses of human origin have long been a subject of study and an object toward which control measures have been directed by public health workers. It is one of the outstanding triumphs of the public health profession that widespread epidemics of typhoid and paratyphoid fevers (the salmonelloses of human origin) are, in general, things of the past. The sporadic case and the undiscovered carrier still persist and are considered important enough for painstaking epidemiological investigation.

A somewhat different attitude exists toward those *Salmonella* infections of man which are of animal origin. As a general rule, those infections attract notice only when a group of people are made ill with an acute infective process following the eating of a common meal or common food. In such outbreaks, generally termed food poisoning or acute gastroenteritis, the causative agent is frequently isolated but the epidemiological investigation seldom elicits adequate proof of the chain of events leading to the specific contamination of the food.

Generally speaking, even less infor-

mation is forthcoming from investigation of the sporadic case of infection with a *Salmonella* of animal origin. Yet these infections are very common and are sometimes severe and of long duration, ranging from the subclinical case to a true typhoidal syndrome. In infants and young children the illnesses produced may be violent and fatal with invasion of any tissue or organ.

Much of the failure to arrive at epidemiological conclusions on which to base control measures may be traced to slow and inadequate laboratory work. This in turn often stems from a commendable caution on the part of the laboratory worker in passing a final opinion on the nature of an organism which cannot be identified rapidly and exactly with materials available commercially. Perhaps more frequently the cause is the tendency of many laboratories to arrive at a diagnosis of "Paratyphoid B" too readily or to class all *Salmonella* cultures except typhoid strains in some pseudo-generic category such as "paratyphoid-enteritidis group." The former designation, when incorrect, results in confusion since it may place emphasis upon the wrong epidemiological approach, and the latter gives too little information for satisfactory follow-up work since the group is ubiquitous in the animal world and,

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-First Annual Meeting, St. Louis, Mo., October 27, 1942.

when applied in so loose a manner, may erroneously include "paracolon" and other organisms of doubtful significance.

Serological classification of the *Salmonella* group is the only logical and complete manner in which a laboratory can meet the problems involved and give true direction to the epidemiologist and to the administrator. Not every laboratory, probably very few, can furnish this service in detail, but many can and should be equipped to do enough serology to identify the main somatic groups of the *Salmonella* genus and to distinguish between the few types of human origin and the many of animal origin. In the United States, this involves as a minimum the serologic recognition of 4 somatic groups, the identification of the typhoid organism and the separation of the true paratyphoid B organism, *Salmonella schottmuelleri*, from the frequently encountered strains of animal origin, principally *Salmonella typhimurium* and certain members of the *Salmonella choleraesuis* group. Even this minimum service will give basic information of real value about 99 per cent of the cultures isolated.

A similar situation was satisfactorily met by public health laboratories when serum therapy was the only accepted specific treatment for the pneumonias. It is now generally recognized that our pneumococcus typing methods were inadequate since we were aware of only 30 pneumococcus types when at least 50 are now recognized (Kauffmann, Mørch and Schmith¹). Certainly if the effort of maintaining about 40 carefully standardized diagnostic sera for that work was practical, it is just as practical to maintain the smaller number of sera needed for recognizing the main somatic groups of the *Salmonellae* and for identifying completely the more common types of importance in human medicine.

The following description briefly summarizes the methods used in Connecti-

cut and the results obtained. The authors have had the benefit of advice freely given by Dr. P. R. Edwards of the National Salmonella Center, Lexington, Ky., who is mainly responsible for the manner in which our serological routine has been evolved, who has furnished us with authentic cultures of the various types and who has typed those strains which we have been unable to identify completely.

IDENTIFICATION OF SALMONELLA GROUP BY CULTURAL AND PHYSIOLOGICAL CHARACTERISTICS

Satisfactory isolations are made from fecal specimens collected in 30 per cent glycerol—0.6 per cent salt solution which is also suitable for the dysentery group. Fecal suspensions are plated on bismuth-sulfite, SS and MacConkey agars both directly and after enrichment in Selenite F. Preliminary identification of *Salmonella*-like colonies is made on the basis of reactions in Kligler iron agar modified by the addition of 0.1 per cent sucrose. After replating for purity the usual tests are made: Gram stain; motility; Voges-Proskauer, indole and hydrogen sulfide tests; fermentation of glucose, lactose, sucrose, and salicin and of other carbohydrates as necessary; and fermentation of dextro-rotatory tartrates.

Positive indole or Voges-Proskauer tests or fermentation of lactose or sucrose exclude the organism from the *Salmonella* group and in general the same is true of salicin fermentation. For exclusion of a true diphasic paratyphoid B strain, utilization of tartrates is a criterion which is seldom wrong and which gives an indication of the probable animal origin of the culture. Serological identification can be made immediately after the purity of the culture is assured and after the organism has been tentatively placed in the *Salmonella* group by means of the tests described above.

ANTIGENIC ANALYSIS

Method for the Diagnostic Test—

The methods for serologic typing are essentially those of Kauffmann.² For the somatic grouping, an alcoholized antigen is used in a slide test. Flagellar reactions are determined with a formalinized broth culture in a tube test after incubation at 50°–55° C. In all cases satisfactory results depend upon proper standardization, and adsorption if necessary, of the typing sera.

Somatic antigens are prepared by emulsifying the growth from an 18–24 hr. agar slant in 1 ml. of absolute ethyl alcohol. The suspension is heated at 60° C. for 1 hr. to inactivate the flagellar components, centrifuged and drained. The sediment is then suspended in about 0.5 ml. of 0.85 per cent salt solution. The test is made by mixing a drop of antigen with a drop of the typing fluid on a glass slide and tilting back and forth for 1–2 minutes. Agglutination is then read macroscopically.

Flagellar antigen is made by adding to an 18–24 hour, actively motile broth culture an equal volume of saline containing 0.6 per cent formalin. For the test, 1 ml. of antigen is added to a tube containing 0.01 ml. of the standardized serum and the mixture is incubated at 50–55° C. Tubes are observed for floccular agglutination at the end of 1 hr. and again after 2 hrs. If tests are incubated for more than 2 hrs., somatic agglutination may yield confusing results.

*Preparation of Immune Sera—*Cultures for rabbit immunization should be plated and checked for smooth colony form. When diphasic cultures are used the strain should also be stabilized in the proper phase, if necessary by cultivation in semi-solid agar containing serum of the type to produce the desired phase variation (Wassen,³ Bruner and Edwards⁴).

For immunization, motile broth cultures are formalinized (0.3 per cent) and injected into rabbits in 0.5, 1.0 and 2.0 ml. doses at 5–7 day intervals. In nearly all instances 3 injections yield sufficiently potent sera and rabbits can be exsanguinated in 2 or 3 bleedings giving a total serum yield of 75–100 ml. per rabbit. Sera and typing fluids are preserved with 0.5 per cent chloroform or 0.5 per cent phenol.

*Standardization of Sera—*For diagnostic typing of *Salmonella* cultures, sera must be used in dilutions which give specific reactions with the main antigens present in the various *Salmonella* types. For somatic tests, titrations are made by the slide test technic described above, using 1:10, 1:20, and 1:40 dilutions of serum, each tested with representatives of the various somatic groups. The dilution which gives a rapid and strong, yet specific, reaction is selected for the typing fluid; a 1:20 dilution is usually satisfactory. For example, serum for the B group may give some cross with the XII antigen of the D (typhoid-enteritidis) group in 1:10 dilution but in 1:20 or higher dilution may react only with the IV and V antigens. Adsorbed sera may be necessary to distinguish between subdivisions of a group as in the case of the E group, all members of which contain somatic antigen III in association with either X, XV, or XIX. If dilutions of the sera will not yield typing fluids specific for the X and XV components, the III antigen must be removed by adsorption. Adsorptions of other somatic antisera have not been found necessary for diagnostic typing.

Sera for flagellar reactions are standardized by the tube test. The serum is tested undiluted and in serial dilutions with representative strains having one or more antigenic components in common with the immunizing strain, including antigens of both phases if the culture is diphasic. The dilution specific for a single flagellar antigen, or for a combination which is of diagnostic value, is selected as the typing fluid.

Adsorbed monovalent sera for flagellar antigens, especially for the non-specific factors 2, 3, 5, 6, and 7, are needed for strain differentiation in occasional instances. For example, *Salmonella oregon* and *Salmonella give* differ from closely related types by only one of several components of the nonspecific phase. Other instances in-

volving either phase of certain diphasic types and even a few monophasic types could be cited.

Application to Diagnostic Typing—At the present time there are 109 types, excluding coliform types,* which have been described in the *Salmonella* genus. These include somatic antigens I-XXXIV and some 64 flagellar antigens. Additional types are continually being added to the list. While the prospect of diagnostic typing may at first appear impractical, actually the majority of types which will be encountered can be classified with relatively few sera.

Table 1 shows the types used for production of sera for somatic grouping that are in use in Connecticut. The

same results can be obtained by using other types to obtain comparable sera. Adsorption has been necessary only with the X, XV, and Vi typing fluids. With an unknown culture, agglutinations are made first with the 8 typing fluids covering somatic groups A-E and their subdivisions. The C group can be split readily into the VI-VII and the VI-VIII divisions by using VIII serum (*amherstiana*). The E group likewise is divided into its 3 subgroups (III X; III XV; III XIX) by agglutination in specific typing fluids. The cultures which do not agglutinate in the 8 sera are tested with the remaining somatic sera. The table also illustrates the manner in which somatic grouping sera may

* Antigenic components in parentheses may be lacking.

* Kauffmann (loc. cit.) lists several (*S. coli* 1-5 and *S. arizona*) in his diagnostic Schema. The authors are not in agreement with this terminology although recognizing the occurrence of *Salmonella* antigens in other genera.

be used for flagellar typing fluids.

Once the somatic group has been determined, sera for the flagellar reactions may be selected readily. Reference to a

list of *Salmonella* types† will show what flagellar antigens occur in the various somatic groups. The most nearly complete list is given by Kauffmann.² Preparation of 10 sera in addition to those also used for somatic typing fluids has yielded a representative group of sera by which all strains that have been isolated in Connecticut can be typed. Included in the group, in addition to those shown in Table 1, are sera for flagellar antigens c, fg, i, k, mt, gom, y, z, and z₂₇, and adsorbed single factor sera for phase 2 components 2, 3, 5, 6, and 7. This list is by no means complete, yet will probably need little revision for use with cultures isolated in other sections of the United States. For the minimum service, flagellar sera for b, d, i, and a nonspecific phase antigen only are needed.

Salmonella cultures frequently have been found upon isolation to be entirely in one phase. In instances when these are not recognizable as monophasic types or cannot be identified unless antigens of both phases are known, phase variation can readily be produced by growth in semi-solid agar containing flagellar antiserum homologous to the phase isolated.^{3, 4} Rarely an adsorption with the unknown strain has been necessary to identify the flagellar antigens. It is to be expected that occasionally a new type of *Salmonella* may be encountered. In these instances, assistance by a National Salmonella Center is essential.

SALMONELLA TYPES IN CONNECTICUT

Salmonella typing was started in 1939 in the Bureau of Laboratories with two objects in mind: (1) to differentiate between true paratyphoid B (*schottmuelleri*) strains and similar types of animal origin, and (2) to determine the

somatic groups to which other strains belonged. Hence, during 1939 there were a number of types which were identified as to somatic group only. During the latter portion of that year, certain cultures were submitted to the National Salmonella Center, Lexington, Ky., for identification. During 1940 the service was expanded and has since been amplified until there is now little need to use the services of the Salmonella Center except to confirm results or to study new types.

Table 2 shows the *Salmonella* types obtained over a period of 45 months (January 1, 1939–September 30, 1942). The two types of human origin, *typhi* and *schottmuelleri*, comprising 56.7 per cent of the total number, are listed first. In all, 23 additional types, presumably of animal origin, have been recognized. Four of these (*california*, *pullorum*, *workington*, and *kentucky*) were the first recorded and amply confirmed isolations from man. Two others (*hartford*⁵ and *simsbury*⁶) were new types never before described but the transiency of the carrier state observed in these cases suggested that these are strains of animal origin. Most of the strains of animal origin listed are frequently encountered in fowl in the United States.

The majority of the animal types were associated with acute infections ranging from mild diarrhea to protracted febrile illnesses similar to typhoid fever. An occasional culture was isolated from an individual apparently in good health. Four types, *california*, *senftenberg*, *simsbury*, and *kentucky*, each represented by only one isolation, were not associated with illness.

Chronic human carriers of animal types have been rare in our experience. The convalescent carrier state was usually of short duration but occasionally it extended over several months. Two individuals have yielded

† The following should be added to Kauffmann's list:

Totals—all types					58	118	92	90	358		

positive stool cultures for *S. barcelly* and *S. worthington* respectively for more than one year; neither of these was acutely ill just prior to the first isolation but both had had intimate contact with domestic animals and both may prove to be permanent carriers. It is interesting to note that two cultures of *S. montevideo* were each isolated from the gall bladder of an individual during surgical operations, an observation which raises the possibility of types of animal origin localizing in that organ in the same manner as species of human origin.

The most important observation to be made from our 45 months' experience is that 43.3 per cent of all new isolations of *Salmonella* types (including the typhoid organism) were strains of animal origin. In other words, in 155 out of 358 cases of *Salmonella* infection, laboratory work indicated that the search for a human carrier as the original source would be of secondary importance and might prove fruitless. By this fact alone, our results prove the value of *Salmonella* typing as a practical diagnostic and epidemiological aid, particularly since

failure to apply antigenic analysis would undoubtedly have resulted in a false diagnosis of paratyphoid B infection or in an incomplete diagnosis in almost one-half the cases studied. To lend emphasis to this point, a number of cultures classified as paratyphoid B in local laboratories have proved to be *typhimurium*, *choleraesuis* or even *oranienburg* in our hands and one "typhoid bacillus" proved to be an anaerogenic *typhimurium*. These had all been "confirmed" by agglutination in commercial antisera.

By a study of Table 2 it will be seen that ability to recognize three serotypes (*typhi*, *schottnuelleri*, and *typhimurium*) would have been sufficient to classify more than 70 per cent of all strains isolated and that the ability to recognize somatic groups B, C, D, and E in addition would have given useful information in 98.9 per cent of cases.

DISCUSSION

Availability of antisera for all known somatic groups of *Salmonellae* has many times enabled us to save much valuable time which would otherwise have been spent in the study of "paracolon" and similar organisms of no proven significance. Many of these are late fermenters of lactose or sucrose so that reporting is considerably speeded up by the early elimination of the possibility of a *Salmonella* type through application of serological methods. Conversely, *Salmonella* antigens have been encountered in coliform and other organisms but always either somatic or flagellar, never both, in a given strain.

Mention has been made of *Salmonella* types isolated from apparently healthy individuals. It has also been pointed out that the carrier state in man is usually transitory for the animal types. This is an important consideration. Let us assume that *S. californica*, an organism with somatic antigens similar to *S. schottnuelleri*, is isolated

from a healthy man who is being investigated as a possible carrier of paratyphoid B. Simple agglutination tests not based upon antigenic analysis would undoubtedly lead to a false conclusion inasmuch as somatic agglutination would occur in paratyphoid B antiserum. The man would, therefore, be considered a paratyphoid B carrier and mistakenly be adjudged the probable source of the outbreak. Besides creating confusion and leading to false epidemiological conclusions, the laboratory report would subject the man to regulatory restrictions of movement and occupation when the strain isolated may very probably have been a transient visitor acquired by close association with infected barnyard fowl or other animals. In Connecticut, even though repeated negative cultures may be obtained following the declaration of the carrier state for paratyphoid B, the carrier cannot be released until a series of cultures taken *at least one year after discovery of the carrier state* is negative. The application of a similar provision to carriers of animal strains seems unnecessary until the permanency of the carrier state has been established for each individual case. It is unjust if, as in the example given above, it rests upon the rather shaky legal ground of a false diagnosis.

Salmonella typing in the public health laboratory raises problems for the epidemiologist who must eventually enlist the services of veterinary and food control officials in breaking the chain of events which leads from infected or carrier animals to infected man. While transmission of animal strains from man to man should not be overlooked as a possibility, the following more probable means of transmission should be uppermost in the thoughts of the investigator: (1) handling of pets and domestic animals; (2) ingestion of raw or incompletely cooked flesh or eggs; (3) contamina-

tion of foods by the droppings of animals such as rats or mice or by flies and other insects; (4) contamination of prepared foods such as cold cuts, salads, and cheese when handled by persons also engaged in dressing fowl and meats.

It is plain that the laboratory services described here will provide the needed evidence for the institution of regulations for the control of the salmonellosis transmissible from animals to man. The framing of such regulations as are feasible is a matter of coöperative effort on the part of public health and veterinary officials. Veterinary bacteriologists and pathologists have already taken the lead in pointing out the importance to man of the animal salmonellosis, particularly those of fowl. Edwards⁷ states: "Several years of work on the *Salmonella* group have disclosed that fowl are the greatest reservoir of paratyphoid infection in the United States." Jungherr⁸ observes: "The control of paratyphoid infections in birds must be viewed from two standpoints, that of man and that of animals."

SUMMARY AND CONCLUSIONS

The value of *Salmonella* typing in a public health laboratory is discussed and the methods used in Connecticut are presented. A public health laboratory should render at least a minimum typing service by which human types may be differentiated from animal types and the main somatic groups (B, C, D, and E) may be recognized. The methods involved are no more complicated than those for pneumococcus typing. Additions to or departure from this basic plan may be desirable in a given locality but should be made only after a sufficiently long experience to obtain a general idea of the types commonly encountered. The assistance of a National *Salmonella* Center should be utilized in any case.

In Connecticut, *Salmonella* typing, originally the minimum stated above, was started in 1939. The results of this service extending over 45 months for a total of 358 cultures have shown: 43.3 per cent of all new *Salmonella* isolations were strains of animal origin, belonging to 23 serotypes; 56.7 per cent were of human origin, represented by 2 serotypes, *S. typhi* and *S. schottmuelleri*. The most common serotypes were as follows: *typhi*, 40.8 per cent; *schottmuelleri*, 15.9 per cent; *typhimurium*, 14.8 per cent. Only 1.1 per cent of the serotypes fell into somatic groups other than B, C, D, and E. Organisms isolated for the first time from man were *S. californica*, *S. pullorum*, *S. worthington*, *S. kentucky*, and two new types—*S. hartford* and *S. simsbury*. Concerning the animal strains, the carrier state in man was rarely prolonged either in convalescents or in healthy individuals and the chronic carrier state is by no means so frequently found as with types of human origin.

Typing of a *Salmonella* culture by means of antigenic analysis is the only procedure by which the laboratory can furnish an authentic report and so save time and effort in the ensuing epidemiological investigation by stressing the relative importance in each case of (1) looking for the human carrier or (2) establishing a chain of events leading from the infected or carrier animal to man.

Isolation of *Neisseria flava* from the Genitourinary Tract of Three Patients*

CHARLES M. CARPENTER, M.D., F.A.P.H.A.

Department of Bacteriology, University of Rochester
School of Medicine and Dentistry, Rochester, N. Y.

THE cultural method for the diagnosis of gonococcal infection has not only proved to be a useful aid in the diagnosis of the disease, but has demonstrated the presence of *Neisseria* other than the gonococcus in the genitourinary tract.¹ In an epidemiological investigation of gonococcal infection in Glynn County, Ga., during the summer of 1941, *Neisseria flava* was isolated from 3 of 505 patients examined for evidence of gonorrhea. These cases were of interest because all 3 patients presented symptoms similar to those of gonococcal infection, but in no instance was *Neisseria gonorrhoeae* observed in either films or cultures.

The essential information concerning each patient is briefly summarized.

Patient Br.—A 37 year old married colored woman who applied to the Board of Health for a "health card" required for employment as a domestic servant. Gonococcal infection denied. Examination revealed extensive cervical erosions and a moderate purulent discharge. Serologic test for syphilis positive. Films from the cervix revealed no Gram-negative cocci. Predominating organism isolated in culture was *Neisseria flava*.

Patient St.—A 17 year old single colored girl who presented herself at the venereal disease clinic for treatment of a profuse vaginal discharge. Venereal disease denied. Examina-

tion revealed slight erosion about the cervical os and a moderate purulent exudate. Films from the cervix showed no Gram-negative cocci, but cultures yielded *Neisseria flava*.

Patient Th.—A 41 year old married white man who came to the clinic for the treatment of a chronic gonococcal urethritis, which failed to respond to sulfonamide therapy. Admitted several previous attacks of gonorrhea. Was under treatment for syphilis at the time of examination. Examination revealed a moderate, creamy-white, urethral exudate, lighter in color than that characteristic of gonococcal infection. Several large venereal warts were distributed over the dorsal surface of the corona, some of which exuded pus similar to that discharged from the urethra. Microscopic examination of films prepared from the exudate revealed Gram-negative diplococci slightly more spherical in shape than the gonococcus. *Neisseria flava* predominated in cultures; this organism was again isolated 6 days later from the same source.

The patients were treated with sulfathiazole, and subsequent examinations revealed no evidence of either *Neisseria flava* or *Neisseria gonorrhoeae*.

The biologic characteristics of the three strains of *Neisseria flava* were similar. Discrete, opaque, pale yellow colonies, slightly flatter than those of the meningococcus, were formed on chocolate-blood agar. The pigment was barely discernible, except when the organisms were grown on a light-colored medium, such as coagulated blood serum. All three strains of *Neisseria flava* fermented glucose, maltose, and levulose

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

and thus were identified as type ii of Elser and Huntoon, or type iv of Gordon.² Microscopically, the cells resembled those of the meningococcus more closely than those of the gonococcus because of their spherical appearance.

DISCUSSION

To our knowledge, this is the first reported instance of the isolation of the type of *Neisseria flava* described herein from the genitourinary tract of man. The recovery of Gram-negative cocci other than the gonococcus from the genitourinary tract has been reported in the literature, but the meager descriptions of the biologic characteristics of the organisms have made identification uncertain. In 1936, Coutts and Barthet³ reported the recovery of "naso-pharyngeal Gram-negative cocci" from the cervix of two prostitutes. One strain produced pale yellow colonies, failed to ferment any of the carbohydrates, was not agglutinated by an antimeningococcal serum, and was identified as "diplococcus pharyngeus flavus III." The biologic characteristics of the second strain were similar, but production of pigment was not mentioned by the authors. Since the isolation of the three strains of *Neisseria flava* described in this report, Lankford⁴ has recovered the organism from semen in two instances.

Neisseria flava is considered to be part of the normal bacterial flora of the upper respiratory tract, and its presence in the genitourinary tract raises some interesting questions as to the source of

the organism and its ability to produce disease. There are at least two possible explanations for its presence in the genitourinary tract, one, that it was carried there from the upper respiratory passages, and the other, that unusual environmental factors over a period of time altered the biochemical activities of the gonococcus in such a manner that it acquired additional enzyme systems. Fundamentally, *Neisseria flava* differs from the gonococcus only in the possession of two additional enzyme systems, one of which permits the fermentation of disaccharides and the other the formation of pigment. The absence of gonococci in the 3 cases reported suggests that *Neisseria flava* was responsible for gonorrhea-like symptoms observed.

SUMMARY

Three strains of *Neisseria flava* have been isolated from the genitourinary tract of three patients with clinical symptoms suggestive of gonococcal infection.

Pyrex Suspensions in Turbidimetric and Colorimetric Determinations

Standards of Comparison for Bacterial Suspensions and in the
Resazurin Test

FRANCIS J. HALLINAN

*Division of Laboratories and Research, New York State
Department of Health, Albany, N. Y.*

IT has been difficult in general laboratory practice to prepare reliable standards of comparison for turbidity and turbidity with color, because, while it is possible to establish an adequate color-range with inorganic compounds in acid solution, materials for the simulation of turbidity are neither so readily available nor so satisfactory. In 1939 Brewer and Cook¹ reported that a suspension of Pyrex glass had been found to be markedly superior in the standardization of typhoid vaccine to the suspensions of silica or barium sulfate ordinarily employed as standards of turbidity. Particles of from 0.5 to 3.5 microns in diameter were suspended in distilled water to simulate suspensions of typhoid bacilli; they did not dissolve or aggregate during a 5 year period of storage. The technic of Brewer and Cook has been adapted to the preparation of stable permanent standards of turbidity in the preparation of bacterial suspensions.² Pyrex suspensions in colored media have also been used experimentally as color standards in the resazurin test used in the grading of milk.³ Other possible uses of the suspensions are as standards of comparison for milk of varying natural colors; alpha-naphthoflavone-iodine adsorption compound, a colored suspension that is formed in a test for residual chlorine in water⁴; colloidal complexes of copper or zinc with sodium diethyldithiocarba-

mate; mixed suspension of silver chloride and silver chromate found at the endpoint of the titration of chloride in water; precipitate of barium sulfate encountered with turbidimetric tests for sulfate or barium. For this latter purpose it would be necessary to modify the procedure of decantation to select the larger particles.

BACTERIAL SUSPENSIONS

The modified technic differs from the original in that it employs a longer period of shaking, by which a suspension may be made to the required density without the tedious process of evaporation, and that standardization is by photoelectric colorimeter instead of by particle counting under the microscope. Variations in particle size are limited by specifying both the turbidity and concentration of the stock suspension. In the experimental studies, series of standards were made for direct visual comparison with various bacterial suspensions — pneumococcus, meningococcus, *Bacterium typhosum*. Turbidity was made equivalent to that of the barium sulfate standards then used⁵ and the suspensions were arbitrarily numbered in ascending order as concentration was increased. Each Pyrex standard was prepared in distilled water and in two colored solutions to match the media used for the bacterial suspensions. Without exception, com-

parisons were made more readily with Pyrex suspensions because of their similarity to the sample in color, particle size, and turbidity. Pyrex standards have now replaced barium sulfate standards. The rate of settling is so slow that frequent shaking is unnecessary. Stability during storage is an added advantage.

PREPARATION OF STOCK SUSPENSION OF PYREX GLASS

Break discarded Pyrex glassware into $\frac{3}{4}$ " or smaller chips. Fill a Pyrex bottle, $6\frac{3}{4}$ " in diameter and fitted with a Pyrex glass stopper, to a depth of $2\frac{1}{2}$ " with chips. Clean the chips and bottle. Just cover the chips with distilled water and shake for two 6 hour periods in a machine operating at 130 cycles per minute with a 2" stroke which should provide for violent agitation of the chips. Use fresh water for each period of shaking. Again cover the chips with distilled water and shake for the third time until the suspension approximates the opaqueness of skim milk; the time required will vary from 24 to 120 hours (not necessarily consecutive), depending upon whether freshly broken chips are used.

Transfer the suspension to 1 liter cylinders, cover, and let stand for 48 hours to allow the coarser particles (2 microns) to settle. Decant supernate; allow to settle 24 hours and decant again. Determine the turbidity of the decanted suspension in a photoelectric colorimeter, Luximeter (L) or Klett-Summerson (KS). Use test tubes and a blue filter with the latter. Dilute with distilled water if necessary to bring L to 40 or KS to 590. If too dilute, return the suspension to

the original bottle containing the glass chips, shake further in the machine, repeat the settling and decantation procedure, dilute to the standard turbidity, and determine the dry-solids content. If less than 0.20 per cent, return the suspension to the cylinders used for the second decantation, mix, and let settle for a shorter period to retain a higher proportion of large particles; if more than 0.25 per cent, use a longer settling period to retain a lower proportion. (The suspension we have actually used is 0.22 per cent. How closely this should be approximated would depend upon the precision required.)

Standards for Bacterial Suspensions

Prepare standards by dilution and calibration in a photoelectric colorimeter as indicated in Table 1. The diluent is distilled water or a colored medium.

Make standards resembling beef-extract or bile-peptone solutions by mixing one volume of diluted stock Pyrex suspension with two volumes of the color solution. Use a dilution of one volume of distilled water with two volumes of color solution for the zero setting of the colorimeter that is used. These suspensions settle slowly and should be mixed after several hours' standing.

Beef-extract broth color solution—Dissolve 1.245 gm. of potassium chloroplatinate (K_2PtCl_6) and 1 gm. of cobalt chloride ($CoCl_2 \cdot 6H_2O$) in distilled water. Add 100 ml. of concentrated hydrochloric acid and dilute to 1 liter.

Peptone-bile color solution—Dissolve 2 gm. of potassium chloroplatinate (K_2PtCl_6) and 3.75 gm. of copper sulfate ($CuSO_4 \cdot 5H_2O$) in distilled water. Add 100 ml. of concentrated hydrochloric acid and dilute to 1 liter.

Dispense the suspensions in round-bottomed vials, 15 or 19 mm. outside diameter, marked

TABLE 1
Dilution and Calibration of Pyrex Suspensions

Turbidity Standard No.	Approximate Concentration of Stock Suspension Per cent	Turbidity as Indicated by Photoelectric Colorimeter Scale Readings	
		Luximeter L	Klett-Summerson KS
0.5	3.32	95	40
1	8.34	89	100
2	18.8	78	210
3	30.0	70	290
4	39.6	63	360
5	52.2	57	420
6	60.5	53	460
7	66.7	50	490

at the initial liquid level (bottom of meniscus), and equipped with moulded screw caps. Since these colored standards are acid, the cap lining must be acid resistant. Examine the suspensions with photoelectric colorimeter at intervals of 6 months, or whenever the level of the liquid becomes lower than the graduation mark on the vial, and adjust the concentration if necessary.

RESAZURIN TEST OF MILK

Successful application of the resazurin test for the grading of raw milk according to sanitary quality is dependent upon reliable standards for color comparison in the range from blue through shades of purple to red, to pink, and to white. It has been found difficult in this laboratory to prepare resazurin-treated milk representing the maximum blue or red upon which Ramsdell based the preparation of his standards.³ Experience with the Pyrex turbidity standards encouraged the hope that these suspensions might also be used as permanent standards simulating milk. The stock suspension was allowed to settle only long enough to remove the coarsest particles. Inorganic color solutions were added to provide a series with which any of the colors encountered in the test could be matched. These standards, given arbitrary numerical designations, were used satisfactorily in a preliminary study of the resazurin test and the

resazurin-rennet test⁶ in natural daylight or under artificial reflected light—a fluorescent “daylight” lamp. They were also used in the field for a year and showed no deterioration in careful comparison with freshly prepared standards.

No attempt has been made to correlate with milk-quality the arbitrary numbers assigned to the color standards. Rather, it is hoped that this correlation and also standardization in terms of an accepted color-recording system may be undertaken by investigators who are studying the test. Certainly the utility of the resazurin test will be more readily determined if the standards can be easily prepared in any analytical laboratory. Davis⁷ has suggested that the establishment of a color standard be delegated to an international committee.

White Suspension—With distilled water prepare a suspension concentrated to resemble skim milk as described in the preparation of Pyrex standards for bacterial suspensions; allow to settle only 5 minutes to remove the coarsest particles. Adjust the concentration by dilution or further shaking so that 1 ml. in 100 ml. has a Luximeter reading of 83 or 84 or a Klett-Summerson reading of 160 to 150.

Blue Suspension—Prepare a concentrated white Pyrex suspension. Adjust so that 1 ml. in 100 ml. has a Luximeter reading of from

TABLE 2

Preparation of Permanent Standards for the Resazurin Test

Color Range	Turbidity Standard	White Suspension	Blue Suspension	Red Solution	Yellow Solution
	No.	ml.	ml.	ml.	ml.
	13	1.85	3.00	0.15	0.00
Blue	15	2.84	2.00	0.16	0.00
to	17	3.83	1.00	0.17	0.00
red	19	4.82	0.00	0.18	0.00
to	21	4.87	0.00	0.13	0.00
milk	23	4.93	0.00	0.07	0.00
color	25	4.98	0.00	0.00	0.025

Note: In the Munsell Color Notation⁸ the turbidity standards were interpreted as follows: No. 13, [5.0 PB] 7/3; No. 15, [7.5 PB] 7.5/4; No. 17, [P] 8/2; No. 19, [2.5 RP] 8/4; No. 21, [5 RP] 8/4. The delicate gradations from No. 17 could not be indicated with the same exactness as for the lower numbers. It would seem that advantage could be taken of the highly developed Munsell notation if a practical field outfit could be developed, for example, colored strips mounted in test tubes for comparable examination with the treated sample.

80 to 82 or a Klett-Summerson reading of 190 to 170. Dissolve 15 gm. of copper sulfate ($\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$) in about 75 ml. of the suspension, add 1.6 ml. of concentrated sulfuric acid, and dilute to 100 ml. with more of this suspension. This should have a Luximeter reading in the same range as the white suspension in a 1:100 dilution. The Luximeter should be adjusted to 100 with a distilled water solution of 15 gm. of copper sulfate and 1.6 ml. of sulfuric acid in 100 ml. Adjust the turbidity, if necessary, by preparing suspensions of higher or lower Pyrex content, maintaining the same concentrations of copper sulfate and acid.

Red Solution—Prepare a distilled water solution of 476 gm. of cobalt chloride ($\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$) and 100 ml. of concentrated hydrochloric acid per liter of solution.

Yellow Solution—Prepare a distilled water solution of 2 gm. of potassium dichromate ($\text{K}_2\text{Cr}_2\text{O}_7$), 38 gm. of cobalt chloride ($\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$), and 8 ml. of concentrated hydrochloric acid per 100 ml. of solution.

Dispense the standards in vials of 15 mm. outside diameter having screw caps with acid-resistant linings and a graduation mark at the initial liquid level (top of meniscus). Whenever the liquid level is low due to evaporation, make up to volume with distilled water. At intervals of 6 months or at any time when portions of the suspension have become so packed that they cannot be resuspended, discard and replace with freshly prepared standards.

SUMMARY

Methods are given for the preparation of Pyrex glass suspensions as standards of turbidity.

Pyrex suspensions in colored media have been substituted for suspensions of barium sulfate in the standardization of bacterial suspensions and have been

employed experimentally in the resazurin and resazurin-rennet tests for the grading of milk. The glass suspensions closely resemble bacterial suspensions in appearance, settle slowly, and remain stable longer than those of barium sulfate. In the resazurin test, Pyrex suspensions in colored media have the advantage of being directly reproducible from readily available materials. Standardization in terms of an accepted color-recording system and in relation to milk-quality is suggested.

Pyrex standards have been found to be stable for at least one year.

Various uses for Pyrex suspensions are suggested.

The Single Line Index as an Administrative Aid*

V. A. VAN VOLKENBURGH, M.D., DR.P.H., F.A.P.H.A.

*Assistant Commissioner, Local Health Administration, New York State
Department of Health, Albany, N. Y.*

STAFF depletion due to the demands of military services requires that the remaining health department personnel train and utilize lay assistants to the fullest extent, thus relieving professional public health workers of minor tasks. Similarly, clerical pro-

single line visible index, is particularly helpful. Arranged in panel form with a guide strip giving the headings for the entries on the separate index strips and utilizing strips and signals of different colors, it is possible to envision at a glance the significant details of each

Courtesy of Remington Rand, Buffalo; and Acme Visible Records, Inc., Chicago

FIGURE 1—Desk stand and a single panel.

cedures may be overhauled profitably and devices adopted to conserve further the time of the administrator and field worker. Such a device, namely, the

individual case as well as the over-all status of the particular public health activity for which it is used. Since the device is a visual aid, it may be likened administratively to the spot map of the epidemiologist.

Single line visible index panels (Figure I) have been in use for many

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

years to provide quick reference for lists of names or cases but only in isolated instances has their use been extended. Such an extension was developed in 1938 at Vanderbilt University to provide a simple method of promptly determining patient attendance and delinquency at syphilis clinics.¹ Impressed by the possibilities of the device, our department proceeded to experiment with it. The first application was in connection with venereal disease clinic data, the panel system now in use representing an amplification of that installed by the Vanderbilt clinic. This proved so useful, the same principle was applied to tuberculosis contact examinations, the inspection and follow-up of violations of pasteurizing plants, case visitation by public health nurses, etc.

It should be emphasized that single line index panels present no new information. Their value lies in bringing together in visual form on a strip $\frac{1}{4}$ inch wide by 6 inches long selected information obtained from the various records, inclusive of action taken in connection therewith, for each case carried. Since the standard 15 inch panel accommodates fifty separate strips on each side, the worker and the supervisor can determine at a glance the progress or lack of progress in connection with the project as a whole, as well as note individual cases needing specific attention. The ease with which tabulations may be made greatly facilitates statistical analysis and the preparation of reports, thus resulting in a saving of time and labor if previous methods of obtaining the same information are taken into consideration.

Decision to make use of single line visible index panels for a particular public health activity depends on the administrator's need for such a tool. While the principle involved may be applied to a variety of public health activities, the purpose to be achieved

must be given careful thought. In designing a panel system, only a minimum number of items should be included and these should be selected carefully to assure adequate evaluation of the project as a whole, as well as of its component parts.

To show how single line visible index panels have been developed by our department for local use, several examples are illustrated in the charts accompanying this article.

USE AS A ROSTER OF TUBERCULOSIS CONTACTS AND EXAMINATION APPOINTMENTS

The panels consist of single line strips arranged by nursing districts, with the cases (blue strips) in alphabetical order, each case being followed by its contacts (buff strips). Two guide strips (salmon color) are inserted at the top of each panel as shown in Figure 2 which is a reproduction of a portion of a tuberculosis roster panel now in use. The first guide shows how a green transparent signal used in connection with clinic examination appointments functions. When placed at the extreme left, it indicates that the case is dead; has moved; is in a sanatorium; or is under the care of a private physician who does not wish the case visited. An entry is made above the surname to indicate the reason. If the signal is placed under a particular month, appointment for examination at the clinic has been made for that month during the current year. If placed under the column headed "Delinquent," the patient failed to keep the appointment and is delinquent. When placed at the extreme right, an appointment has been scheduled for a future year and the appropriate penciled entry is made after erasing any previous notation in this column. At the first of the new year, signals are moved to the proper month position for the then current year. The absence of the green

FIGURE 2—Panel as tuberculosis contact roster and follow-up on clinic appointments. Cases on blue strips; contacts on buff. As color could not be photographed, contacts are indented.

signal on a strip indicates that no appointment for examination has been scheduled.

The second guide strip at the top of the panel gives the headings for the entries to be made on the index strips, most of which are self-explanatory. It has been our practice to post the address of the case but to omit posting the address of the contacts unless different from that of the case. The item "color" is omitted in areas where it is not a factor. Under the heading "Act. or Source," the entry on the case strip indicates the degree of infectivity of the case and is posted in code; whereas for the contact strip, the initials of the source case are used. If a case has no contacts, the entry "O" is also posted in this space. Under the

column headed "Yr. Rep.," entry of the year reported is posted for cases; whereas for contacts, the year added to the record is used. Examinations prior to the installation of the panels are noted by posting the year of the last known examination under the heading "Last Yr. Exam." with an entry directly above this figure to indicate the total number of previous examinations. Subsequent examinations are shown by entering the year in one of the four columns provided for this purpose. A tally mark is placed above this entry to show the number of examinations made during the specific year. Advance appointment dates are entered in the last column of the strip. It has been our practice to make all entries in pencil for items subject to

change. To care for contacts discharged from supervision, the contact strips with notation of the reason for discharge are placed at the bottom of the panel to await tabulation before being destroyed. If a contact is found to be a case, the contact strip is moved to the discharged section of the panel

and a case strip is inserted in the active section. An entirely separate panel or section thereof, not shown in Figure 2, with strips of a third color is used for clinic registrants who are neither cases nor contacts.

With the foregoing explanation in mind and a reasonable amount of prac-

tice, it is possible to review the panels quickly for significant factors, and to sum up as to the adequacy of control activities in a particular area. Contacts never examined as well as those examined excessively stand out boldly. Failure to have contacts adequately examined where exposed to a case with positive sputum as well as the need to separate such case from its contacts is immediately evident. Similarly, examination of a disproportionately large number of contacts from the youngest age group (0-14 years) can be demonstrated and attention called to the need for adult contact examinations where efforts may be spent more profitably. Cases lacking an entry as to the activity of the infection and therefore the degree of infectivity, signal a need for a review of such cases with the tuberculosis clinician. Contacts delinquent for examination, if occurring in appreciable numbers indicate the need of further study and possibly nurse instruction in the technic of scheduling appointments or perhaps the formation of night clinics in areas where delinquency is confined chiefly to adult males.

Tabulations may be made quickly by sex and age groups of contacts previously examined, those examined during the current year and those examined for the first time during the current year. Other possible summaries include contacts discharged with reasons therefor, contacts added during a current year and number examined, contacts of cases reported in the current year and number examined and number of cases for which contacts are un-

known. Such tabulations will aid the administrator in assuring a vigorous program for the eradication of tuberculosis.

USE AS A CLINIC RECORD OR GUIDE FOR INSPECTIONS AND VISITS

Simple but useful employment of index panels to visualize pertinent data relative to the clinic attendance of venereal disease cases, the supervision of pasteurizing plants and the visitation of cases by nurses is shown in Figure 3. Limitation of space permits reproduction of only a portion of such panels; therefore, the explanatory information at the bottom of the charts is confined to the material shown and does not cover obvious omissions concerning other contingencies. The purpose of displaying additional examples is to suggest possible ways in which single line visible index panels may be profitably utilized, leaving it to the ingenuity of the individual to develop a system of guide strips and colored signals to satisfy particular needs.

SUMMARY

The use of single line visible index panels permits the worker and supervisor to evaluate at a glance the status of the particular public health activity for which it is used as well as to note individual cases needing specific attention. Since the device is a visual aid, it may be likened administratively to the spot map of the epidemiologist.

Ways to Community Health Education*

MANUEL GONZALEZ-RIVERA, M.D.

Supervisor General, Federal Department of Health, Mexico City, Mexico

THE field of health education is so wide in its scope, and its activities are so multiple and complex, that it is impossible for a single method or a standard procedure to be useful in all the cases and circumstances; consequently, the ways to health education are many, and extremely varied.

In the present chart I have endeavored to classify schematically the ways which a health educator—either a health officer, a nurse, or a social worker—should have in mind to carry on his duties in the field, or in the classroom.

I think that Health Education, in general, comprehends two great groups of activities: Health Propaganda and Health Instruction. The first one includes both Health Information to individuals and Health Publicity to a community as a whole. Health instruction is concerned with school and college health education and with the training of professional personnel; i.e., physicians, engineers, dentists, midwives, inspectors, nurses, and teachers. The technic of both health propaganda and health instruction can be comprehended in two main items:

A. ACTUAL PRESENTATION OF TOPICS

In this item are included all the ways and means through which a topic or theme is actually presented or exhibited

to any audience. The topic in question can be presented in two different ways: (a) By display of objective materials, as in an exhibition of a definite sort of materials in windows or cases, e.g., clothes for maternal and child hygiene use; different kinds of diets for nutrition, and dietetic suggestions; or (b) by demonstration, as to the correct use of a toothbrush in mouth hygiene; the methods of preparation and cooking of foods before a mother's club; training of health officers and nurses in health districts, etc.

B. DESCRIPTION OR REPRESENTATION OF THE THEME

The theme or topic is represented in a manner designed best to attract and sustain the attention of the public. This aim or objective can be attained by auditive, visual, or audio-visual aids, or by other miscellaneous devices:

AUDITIVE AIDS

Among the auditive aids the spoken word sometimes may be coördinated with music and poetry, because the rhythm of a poem and the melodies of music are two excellent ways to carry any message to an individual, to an audience, or to the general public.

Oral propaganda, as well as instruction, can be delivered in two ways:

1. *Direct*, as when the educator—public health worker or teacher—speaks face to face, directly to a definite, particular, individual or group of persons; in this way, a person's word can be

* Presented at a Joint Session of the American School Health Association and the Public Health Education and Public Health Nursing Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

delivered in the most favorable conditions both for the educator and for the audience: the speaker is able to explain and to illustrate the theme as extensively as it is pertinent to do so; he is in position to strengthen his arguments or to appeal vigorously to his listeners when doubt arises among them, or when boredom or indifference is shown by the attendants; he has the opportunity to adapt the substance and manner of presentation to the intellectual level of the audience.

2. *Indirect.* When the educator talks to an invisible person or crowd, as through a microphone, telephone, or phonograph record, he is following an indirect method of propaganda and instruction; under these circumstances, any talk or address must be short and clear; laconic, if necessary; energetic, penetrating, more appealing and more suggestive than documentary.

Direct instruction and propaganda can be *indoors* and *outdoors*; it is very important that the educator have in mind this fact, because there is a great difference in the kind of attention paid and the interest taken by the audience when it is addressed in a comfortable, well located place, seated in easy chairs, and when given outdoors, standing in a square or in a parade ground.

VISUAL AIDS

Visual aids to health education are essentially the printed word, pictorial procedure, and models.

1. The printed word, as used in health education, is delivered to individuals or to the public in the form of letters, booklets, leaflets, folders, magazines, journals, books, etc.

Printed material may be delivered to determined groups of persons or addressed to names taken from directories or selected mailing lists: this excellent way of distributing propaganda is called *personal* or *direct*.

It is entirely different when materials

are delivered to a *general* public or distributed to a promiscuous crowd.

When printed material is distributed to the general public without any discrimination whatsoever, it is done with the hope that a large number of persons have time and willingness to make good personal profit of it; for this purpose fliers, leaflets, folders, and newspapers are distributed, and many other materials destined to be read.

Another way to use printed material as an educational tool is when it is exhibited to the public in places in which there are chances for it to be seen; this kind of propaganda must be extremely brief; very attractive and appealing; showing the topic at a glance, in such a manner that "he who runs may read." This is the way and kind of propaganda to be glanced at.

Materials to be glanced at may be exposed in an intramural environment in the form of posters placed in waiting rooms, inside vehicles, etc., or in extramural places.

The extramural propaganda sometimes can be ambulatory, as that conveyed by men in streets, or outside of buses or trucks; but more commonly it is used in fixed form.

The materials fixed in places in which they are easily destroyed are called transitory, while those more or less enduring constitute a permanent propaganda, like electrical signs, frescoes painted on a wall, posters along a highway, stone signs on the top side of a hill, etc.

2. Pictorial propaganda is based upon pictures or drawings which may represent things or living beings, or may be graphics of deeds and events.

Pictures of things or living beings may be representative of the topic, as a photograph or sketch of a privy in the educational material used with sanitation purposes; it may be purely decorative, as are landscapes; it may be symbolic or allegorical, as the picture of

a monster representing an illness; it may be suggestive, e.g., the well known dog listening and recognizing "his master's voice," which suggests to the public the high fidelity of sounds in certain phonograph records.

Deeds and events may be represented by pictorial statistics, or by a descriptive or narrative series of pictures, as in graphical stories, film strips, and silent movies.

3. There are many instances when things can be very attractively shown in three dimensions: models, lay figures, statuettes, and even monuments or memorials serve for this purpose.

AUDIO-VISUAL AIDS

On using audio-visual aids as a way to health education, both senses, sight and hearing, are employed as happens when attending a demonstration or a

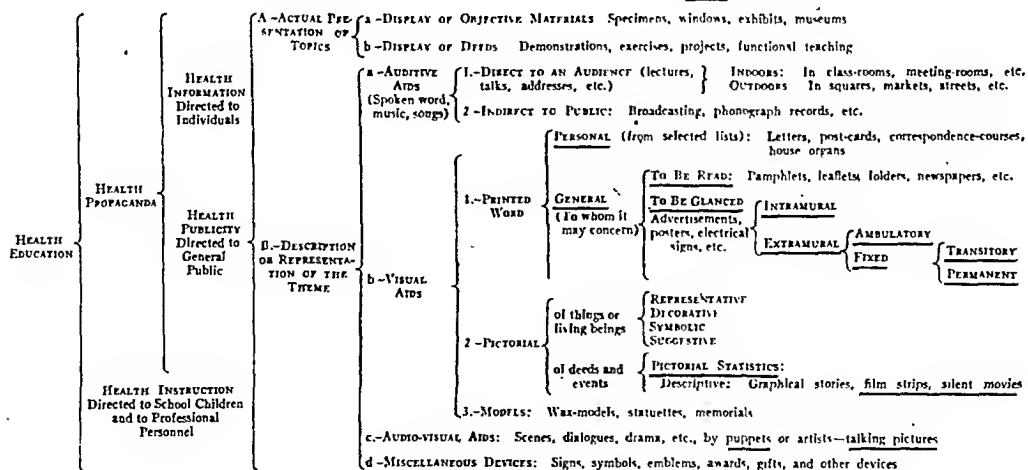

show by puppets or artists. One of the most useful popular and economical forms of health education is talking pictures. For rural health education silent moving pictures are better, provided they are explained personally in plain and easy language by health educators.

MISCELLANEOUS DEVICES

In the item marked miscellaneous devices I include those many and varied "tricks of the trade" like emblems or symbols; dainties for the children; diplomas or other rewards for the winners in health contests; and many other gadgets we are obliged to use in our health educational work, to call the attention, to sustain the interest, to stimulate into action either a person or a group; in short, to attain our goal, i.e., the health and happiness of our people, of all our brethren of the Americas.

Methods of Transmitting Material to a Laboratory for Gonococcus Cultural Studies*

OSCAR F. COX, M.D., AND MARY V. McDERMOTT

Chief, Genito-Urinary Clinic, and Research Bacteriologist, The Boston Dispensary, Boston, Mass.

A PREVIOUS report¹ on the results of 123 controlled experiments described a method for sending material through the mail for gonococcus cultural studies. One hundred and sixteen additional experiments with slight modifications in technic have since been completed. The technic now used is as follows:

Mix equal amounts of sterile distilled water and defibrinated horse blood. Then add, of 1 per cent aqueous solution of crystal violet, sufficient to make a dilution of 1:30,000. Autoclaving is not necessary, since a 1 per cent solution of crystal violet is likely to remain free from growth. Five mg. of para-amino-benzoic acid are then added to every 100 ml. of the blood-dye solution. Test tubes 6 x 50 mm. are used with cork stoppers to fit (No. 000XXX). Autoclave the tubes which are to contain the blood-dye solution at 15 lb. for 20 minutes. Use a 100 ml. burette to fill tubes approximately two-thirds full (0.6 ml.) with the blood-dye solution. Plug with cork stoppers which have been previously dipped in melted paraffin and kept under 70 per cent alcohol. Invert tubes and seal stoppers with hot

paraffin. A similar number of tubes is used for keeping swabs sterile. Dip cork stoppers in melted paraffin. Cut round toothpicks in half, make swabs at cut ends of toothpicks, and insert pointed ends into stoppers. Place swabs attached to stoppers in test tubes and autoclave at 15 lb. for 20 minutes. Invert tubes and seal stoppers with hot paraffin.

Some difficulty has been caused by the fact that different lots of crystal violet vary in their bactericidal and bacteriostatic properties. The dye used in our experiments was obtained from the National Aniline and Chemical Company, and the lots with an approximate 84 per cent dye content gave the best results in dilutions of 1:30,000. Each new lot of dye is tested by the following method: Swabs of known positive exudates are put into tubes which contain various dye dilutions in the horse blood and water solution. The tubes are kept at room temperature for 24, 48, and 72 hour intervals, after which the swabs are planted on chocolate agar plates which are incubated for 48 hours. The dye dilution that causes the greatest inhibition of streptococci and staphylococci and at the same time permits the gonococci to remain viable is selected for use.

Another difficulty is the technic of obtaining specimens. In the case of

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

females we have had our best results when the cervical canal has been wiped clean with sterile cotton and the fresh material from the deep cervical glands has been utilized. When this method was not followed there were frequently more extraneous microorganisms than could be inhibited by the 1:30,000 crystal violet.

Results with 116 exudates are shown in Table 1.

TABLE 1

*116 Delayed Cultures of Exudates**(All Control Cultures Positive for Gonococci)*

Hours Delayed	24	48	72	...
Number of Cultures	45	51	20	116
Number Negative	2	5	2	9
Number Positive	43	46	18	107
Percentage Positive				92

In the previously reported experiments gonococci were detected by culture in 115 of the 123 exudates that had been in the blood-dye solution from 13 to 72 hours before planting. These and the 116 additional experiments now completed give a total of 239 controlled experiments in which gonococci were detected in 222 plates that were not planted until the exudate had been in the blood-dye solution from 13 to 72 hours, or an efficiency of 93 per cent.

Allison, Charles, and Carpenter² have reported their experiments on the survival time of gonococci in urine in male patients. They worked with uncentrifuged urines and urine sediments. Some of each were kept at 4° C. and at room temperature from 1 to 48 hours before planting. The authors report the survival of 100 per cent of 86 strains up to 3 hours, 84 per cent at 12 hours, 41 per cent at 24 hours, and 2 per cent at 48 hours. When, however, urine specimens were centrifuged and the supernate discarded, gonococci were recovered from 88 per cent of the 17 sediments that had been kept at 4° C.

for 24 hours. The authors reported that the pH of the urine had little if any influence on the results.

Recently we have experimented with delayed cultures of urine specimens. The following technic has been used for collecting these specimens. A patient with a urethral discharge voids into a wide-mouthed sterile receptacle. If no discharge is present the prostate and urethra are stripped and the prepuce is retracted before the patient voids. The glans penis is not cleansed. Into several tubes, each of which contains 1 ml. of defibrinated horse blood, water, and different dilutions of crystal violet, is poured 1 ml. of the urine.

Preliminary studies carried out from June 5 to June 15 revealed that when the urine was combined with the blood-dye solution in strengths greater than 1:120,000 the gonococci were inhibited, but in dye dilutions of 1:120,000 to 1:600,000 the results were sufficiently encouraging to warrant further investigation.

From June 16 to August 1, 320 urine specimens, all of which contained gonococci, were mixed with equal parts of a solution consisting of two-thirds defibrinated horse blood and one-third water. Five mg. of para-amino-benzoic acid were then added to every 100 ml. of the resulting solution. Varying amounts of crystal violet were then added to make, when diluted with the urine, dye dilutions of 1:120,000 to 1:600,000. The tubes are kept at room temperature for 24, 48, 72, or 96 hours, at which times they are centrifuged and the supernate discarded. The sediment is then shaken onto both chocolate agar and starch agar plates which are streaked with a platinum loop. Controls consist of 1 ml. of the same urine specimen which is centrifuged, supernate discarded, and the sediment planted immediately. All plates are incubated under an increased CO₂ tension. Lighted candles in museum

jars are used for this purpose. Plates are read after 48 hours' incubation and suspicious colonies are examined by Gram-stained smears and fermentation tests.

Our results with urines are shown in Table 2. We found that the pH of the urine had no effect upon the results.

Exudates sent to us through the mail in the blood-dye solution were planted in our laboratory. In one instance the delayed culture was negative and the smear was reported positive, and 26 of the delayed cultures were positive when the smears were reported negative. In other words, gonococcal infection that would otherwise have been missed was

Summary					
No. Planted at 24 Hrs. (Exclusive of 1:600,000 dilution)	111	Positive	97	(87%)	
" " " 48 "	54	"	41	(76%)	
" " " 72 "	57	"	40	(70%)	
" " " 96 "	52	"	35	(67%)	
Total	274	"	213	(78%)	

Not included in the above, but possibly worthy of mention, were 56 urines and exudates from patients with active gonorrhea, in which all delayed cultures were positive and 3 routine cultures of exudates and 12 routine urine cultures were negative. Routine cultures were planted within 1 hour after obtaining the material from the patient. During the interval exudates were kept in proteose No. 3 peptone broth.

Routine physical examinations of 367 women inmates of a state institution included cervical smears and cultures.

found by the blood-dye technic in 7 per cent of 367 women inmates.

In a series of exudates from 36 patients, sent to us in the blood-dye solution from a venereal disease clinic located in another city, 6 (16 per cent) of the patients with negative smears were found to be positive by culture.

SUMMARY

We feel that the blood-dye method for transmitting exudates through the mail for gonococcus cultural studies is more efficient than the smear method

in detecting such organisms in women, and in men with chronic or latent infections. We do not at this time recommend the sending of urine specimens through the mail for gonococcus cultural studies as a routine procedure.

However, our experiments with this method justify further study.

Accidents in the United States

"It is discouraging to observe that at least as many persons died from injuries sustained in accidents every month in 1942 in the United States as there were civilians mortally wounded by enemy air raids on Great Britain in any one month of the war so far. As a matter

of fact, in several months our accident toll exceeded by 1,000 deaths or more the 6,955 British air raid fatalities suffered in September, 1940, when they were at a peak figure." *Statistical Bull.*, Metropolitan Life Insurance Company, December, 1942.

Action of Finely Divided Magnesium upon the Lungs^{*}

LEROY U. GARDNER, M.D., F.A.P.H.A.,
AND ANTHONY B. DELAHANT

*The Saranac Laboratory for the Study of Tuberculosis,
Saranac Lake, N. Y.*

THE recent papers of McCord, Pendergast, Meek, and Harrold,^{1, 2} and of Schultz and Walter³ have focused the attention of American industrial hygienists upon the hazards from metallic magnesium. Their experiments and the observations of several foreign experimenters and clinicians have demonstrated that small particles of this metal embedded in living tissues dissolve with the evolution of hydrogen and the production of an irritating alkaline hydroxide. The tissue response consists of a transitory, acute inflammation which is unique because of the presence of large vacuoles produced by the presence of the gas. When all the metal has dissolved, the inflammation subsides and healing ensues. The amount of residual scar tissue is proportional to the severity of the injury which in turn depends upon the quantity of metallic irritant.

These observations led to the suspicion that dust created in manufacturing and machining magnesium and magnesium alloys might be injurious to the lungs. Inquiry revealed that such hazard could hardly exist in the manufacture of powdered magnesium because the danger of fire and explosion precludes exposure of workmen to appreciable atmospheric concentration of this

mineral. In processing these metals, it was found that many of the operations are not productive of much fine dust. When particles small enough to be inhaled are produced it seems highly improbable that the result observed in the subcutaneous tissue could be duplicated in the lungs. The finest dust would theoretically dissolve on contact with water vapor in the nose, trachea, and large bronchi, liberating hydrogen at points where it could be readily exhaled. Undissolved particles that might reach the terminal air spaces would again exert their specific effects where no pressure could develop. Permanent injury to the pulmonary framework could only result from undissolved magnesium particles which might finally be transported into its structure.

The validity of this reasoning has been tested in a series of experiments upon animals. Actual inhalation of magnesium in the form of dry dust has not been feasible, owing to the danger of explosion, but the same objective could be attained by introducing salt solution suspensions of fine magnesium particles through a tracheal tube. Before making such tests, the capacity of the particular material to produce "gas tumors" was tested by subcutaneous injections.

Procedure—The powdered magnesium used had been ball-milled to pass a 200 mesh screen. The particle size ranged between 1 and 100 microns, the average

^{*} Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

being about 30 to 40 μ , with a moderate amount under 4 μ . Two, 5 and 10 per cent suspensions of this material in 0.85 per cent NaCl solution were prepared immediately before injection. Sterilization was omitted because of the rapidity of solution in a fluid medium. The guinea pigs of the first two groups received injections of approximately 0.5 ml. each; for the cats of group C, the dose was 2 to 3 ml. However, these dosages could not be gauged accurately because of the marked tendency of the larger particles to settle out in a syringe.

Group A—Six guinea pigs injected subcutaneously in the groin; dose approximately 10 mg., killed at intervals of 1, 2, 3, 4, 7, and 21 days.

Group B—Ten guinea pigs injected into the lungs by means of a long flexible needle passed through the larynx and trachea into a stem bronchus without anesthesia; approximate dose, 10 mg. One animal died of pneumonia on the 9th day; the others were sacrificed at the following intervals after injection: 24 and 48 hours, 1, 2, 4, 12, and 16 weeks.

Group C—Five cats injected similarly by tracheal catheter through a small bronchoscope; approximate dosage

FIGURE 1—Reaction in subcutaneous tissue to 10 mg. of magnesium powder at the following intervals after injection: A, 1 day; B, 2 days; C, 3 days; D, 4 days; E, 7 days; F, 21 days. Gas bubbles in A through D. Some chronic inflammation in E. Tissue practically normal in F.

FIGURE 2—Reaction in lungs 24 hours after intratracheal injection of 10 mg. magnesium powder. Note areas of pneumonia in the lobes on the upper and lower right.

ranged 100 to 250 mg. One of them received 1.5 ml. of a 10 per cent suspension and was killed 1 hour later; the other 4 were given about 2 or 3 ml. of a 5 per cent suspension. These last were killed after 48 hours, 6, 8, and 10 weeks.

None of the animals showed any symptoms after the injection, and as noted there was only one death from pneumonia, which occurred 9 days after intratracheal injection. The tissues of all of them were preserved and examined microscopically.

FIGURE 3—All trace of pneumonic reaction has disappeared 4 weeks after injection of 10 mg. of magnesium powder.

Group A guinea pigs demonstrated that this material would produce the typical emphysematous reaction reported by the previous observers. Twenty-four hours after injection, large gas blebs surrounded by acute inflammatory reaction had developed in the subcutaneous tissue. These changes persisted for 3 days. By the 4th day, the blebs were barely visible and healing had begun, as evidenced by proliferation of fibroblasts at the margins of the lesion. At the end of a week, only granulation tissue marked the site of injection and by the 3rd week, practically all traces of reaction had disappeared.

Group B—Guinea pigs in which the same quantity of magnesium was injected directly into the pulmonary air spaces showed comparatively little reaction. In areas where the suspension of particles had lodged, pneumonic reaction developed which persisted in acute form for about a week. Much of this effect was nonspecific in character and was obviously due to the fluid. In extent and severity, it was no greater than many reactions excited by suspensions of more inert particles. The unique feature in these experiments was the early appearance of microscopic vacuoles within the cytoplasm of mononuclear cells projecting from the inner surfaces of the air space walls. Likewise, many of the free wandering phagocytes were fragmented and some showed cytoplasmic vacuoles. Such changes were well defined during the first 2 days but had disappeared by the 7th day. At the latter interval, there was still some evidence of more chronic inflammatory tissue changes, but thereafter the healing and absorption of such elements was progressive. By the 4th month little remained except microscopic thickening of the airspace walls. An exception was noted in one animal, killed 2 weeks after injection, which showed an isolated pulmonary abscess of microscopic dimensions. This lesion was surrounded by

granulation tissue; at the edge of its necrotic center there were still vacuolated mononuclear phagocytes and small giant cells. Minute particles that were presumably magnesium were visible for 1 week; thereafter none could be found.

Group C—The 5 cats in this series showed less reaction of a character similar to that in the guinea pigs. Forty-eight hours after injection vacuoles were prominent in both sessile and free phagocytic cells. Small giant cells had formed about the larger metallic particles, and where the latter had dissolved vacuoles were left. By the 6th week, healing was practically complete, and at the 8th and 10th week nothing remained to mark the site of injury.

COMMENTS

The experimental procedure might be criticised on the grounds that all of the particles of magnesium were not of inhalable dimensions and that they were not sterilized before injection. However, the work of the previous authors cited had amply demonstrated the nature of specificity of the magnesium reaction, and our subcutaneous injections in group A guinea pigs indicated that it was being reproduced. The results in this group also proved that the dosage and particle size were adequate to cause characteristic changes in the subcutaneous tissues. When essentially the same, or in the case of the cats 10 to 25 times this amount of magnesium was introduced into the air spaces of the lung tissue, reaction was much less severe. The alkaline hydroxide was irritating, as manifested by localized patches of pneumonia, but as soon as the soluble irritant had been diluted and removed, inflammation subsided and healed. The specific effects of hydrogen gas were manifested in isolated cells which, because of the peculiar anatomy of the lungs, could be blown to pieces without exerting significant pressures upon surrounding tissues. While the involved

phagocytic cells were killed, thereby adding a further source of irritation, the fact that healing with resolution had occurred within 6 weeks demonstrates the comparative innocuousness of the process. Evidence of injury to the fixed tissues of the pulmonary framework is lacking so that one must conclude that very few particles reached such structures.

Since the reaction to a very large number of magnesium particles introduced into the lungs without trauma in a unit time is so slight and transitory, it is hard to imagine much effect from the smaller number of particles that might reach the pulmonary air spaces by inhalation. Presumably the phagocytes would be destroyed as fast as they ingested particles of the mineral, but others are always available to take their place. The concentration of irritant, both from the metallic particles and the injured phagocytes, would probably be too low to cause much inflammation. The possibility of disabling fibrosis from irritation of fixed tissues is very remote.

CONCLUSION

Finely divided metallic magnesium does not have the same effect upon the lungs that it exerts in the more dense subcutaneous tissues. The absence of "gaseous tumor" formation is explained by the free communication of the pulmonary air spaces with the external air. Even if manufacturing processes permitted inhalation of an appreciable amount of magnesium dust, it is highly improbable that serious injury of the lungs will ensue.

AND FRED W. GRAVES, D.V.M.

New York State Department of Health, Albany, N. Y.

IN the twenty-five year period, 1917-1941, a total of 168 outbreaks of milk-borne disease have been investigated by the New York State Department of Health. A milk-borne outbreak is defined as one demonstrated to have been transmitted by a common milk

the use of raw milk except two of typhoid fever, one of bacillary dysentery, and one of scarlet fever. The typhoid fever and bacillary dysentery outbreaks were due to pasteurized milk contaminated after processing, and the scarlet fever outbreak resulted from milk

supply and to have affected persons residing in more than one household. Ten thousand residents of the state, exclusive of New York City, were affected in these epidemics, the smallest involving 3 persons and the largest an estimated 1,100 individuals.

All the 168 outbreaks were traced to

labeled "pasteurized" although evidence indicated that it had not been properly processed.

Table 1 presents the distribution of outbreaks according to the type of milk-borne disease and the number of cases resulting. Although typhoid fever and paratyphoid fever have caused the largest number of outbreaks, 45.2 per cent of the total, only 12.1 per cent of the cases have been due to these diseases. Septic sore throat and scarlet fever outbreaks, comprising 34.0 per cent of those studied, contributed 68.2

per cent of all cases. It is apparent, therefore, that these hemolytic streptococcus infections present the most important public health problem in the upstate New York area in terms of cases of illness resulting from outbreaks of milk-borne disease. Furthermore, very few milk-borne outbreaks of typhoid fever have occurred in recent years, so that hemolytic streptococcus outbreaks have assumed even greater relative importance.

In recent years, the Lancefield classification of hemolytic streptococci¹ has been utilized extensively in the search for the source of milk-borne outbreaks of scarlet fever and septic sore throat. By this means, beta hemolytic streptococci falling into Group A, the group including approximately 95 per cent of strains pathogenic for man, may be distinguished from those belonging to other groups. The value of this serological procedure is emphasized by the findings of Sherman and Niven² who have reported that beta hemolytic streptococci may be recovered from as high as 8.5 per cent of samples of commercial pasteurized milk, and 18.0 per cent of similar samples of raw milk. The prevailing strains isolated by these authors from pasteurized milk proved to be Group D and from raw milk Groups B and C.

The differentiation by Griffith³ of the various hemolytic streptococci pathogenic for man into 30 or more serologically specific types has not only provided a more exact means of identi-

fication of the source of milk-borne outbreaks but also has permitted further study of the epidemiological characteristics of the different strains of these organisms. Since the introduction of this procedure, at least six reports of its use in conjunction with the investigation of apparently milk-borne outbreaks have been published and are summarized in Table 2.

All of these epidemics have been reported in the foreign literature. It is of interest to note that three of the six were attributed to Griffith Type 2 strains.

For a number of years, the Division of Laboratories and Research of the New York State Department of Health has undertaken the collection and preservation of strains of hemolytic streptococci recovered during the course of the epidemiological investigation of milk-borne outbreaks. This procedure permitted Stebbins to identify retrospectively by Griffith typing the specific strains of hemolytic streptococci encountered in certain earlier investigations.¹⁰ Since July, 1940, an attempt has been made to conduct this phase of the study immediately following the recovery of the presumptive causative organism. A tabular presentation of the studied epidemics is given in Table 3.

Griffith's Type 3 hemolytic streptococcus has been identified more frequently than any other single type, being encountered in three of the nine outbreaks investigated.

Each of the outbreaks enumerated

* Cross-typing

† Typing inconclusive but strongest agglutination with type 19 antiserum

provides interesting data relative to the epidemiological characteristics of milk-borne epidemics due to serologically typed hemolytic streptococci. The present report, however, will be limited to various phases of one of the more recent smaller outbreaks; namely, that which occurred in Cannonsville, Delaware County.

CANNONSVILLE OUTBREAK

During April, 1942, a small milk-borne outbreak of hemolytic streptococcus throat infections occurred in this relatively isolated rural community of approximately 275 inhabitants. It thus provided a unique opportunity to investigate the distribution of hemolytic streptococci among the general population. Moreover, the incriminated milk was found to have been secured from a large cheese plant handling milk from 356 producers, making the determination of the actual source of infection a distinct challenge.

Records of illness were obtained by house-to-house survey for 28 of 197 persons interviewed in Cannonsville and

for 16 of 42 individuals in the surrounding area. Thus the outbreak involved 44, or 18 per cent, of the 239 persons included in the study group. Seventy-seven per cent of the cases occurred in persons 15 years of age or over, and 61 per cent among males.

All of the cases occurred during the 3 week interval between April 5 and April 25. The dates of onset are shown graphically in Figure 1.

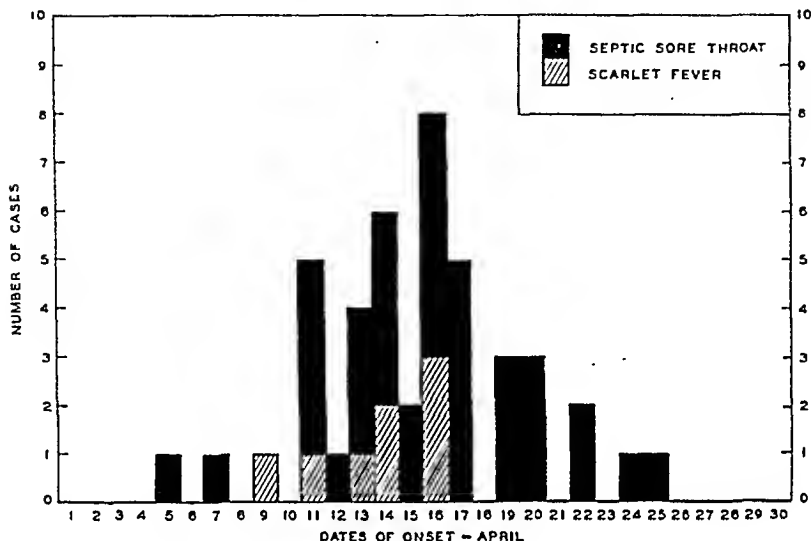

Thirty-seven of the 44 persons affected had first symptoms between April 11 and April 20, the peak daily incidence of 8 cases occurring on April 16.

CLINICAL CHARACTERISTICS

Illness was characterized by sudden onset of sore throat, fever (up to 103° F.), headache, cervical lymphadenopathy, and generalized arthralgia and myalgia. No deaths occurred among the 44 cases. In 8 instances, scarlatinal rashes were observed and, since the causative organism thus demonstrated its ability to elaborate erythrogenic toxin, this observation again indicates how illogical it is to distinguish between

FIGURE 1

DATES OF ONSET OF 44 CASES OF HEMOLYTIC STREPTOCOCCUS THROAT INFECTIONS
CANNONVILLE, DELAWARE COUNTY
APRIL, 1942

cases of septic sore throat and scarlet fever.

A striking characteristic of the outbreak was that of the joint manifestations experienced by 16 patients, or more than one-third of those ill. In some instances, only transient involvement of one or two joints with pain and limitation of motion was noted but in others severe polyarthritis was experienced with swelling, redness, and tenderness about the joints. In this category, 4 cases of migratory joint involvement clinically suggestive of active rheumatic fever were observed and the persons so affected experienced an asymptomatic period of 1 to 2 weeks between throat symptoms and these joint manifestations. One of the persons affected had previously experienced an acute attack of rheumatic fever.

Throat cultures were secured from 35 of the 44 cases either at the time of, or shortly after, the acute episodes of sore throat. Twenty-three of these yielded hemolytic streptococci, 17 of which were identified serologically as Lancefield Group A, 2 Group B, 3 Group D, and

1 could not be classified. Fifteen of the 17 Group A strains were established as belonging to Griffith's Type 3, thus indicating this organism to be the epidemic strain; the 2 remaining Group A strains proved refractory to typing.

INCRIMINATION OF MILK SUPPLY

At the outset of the investigation, it was apparent that the cases occurring in the outbreak were particularly concentrated among workers in the Q cheese plant. This plant, employing 30 workers, constituted the sole large commercial establishment in the area and, with the exception of dairy farming, constituted the principal source of livelihood of the residents of the community.

Milk used in Cannonville was found to be almost exclusively unpasteurized. Many families obtained milk from their own cows, a few purchased small quantities from three small dealers in the community, and the remainder of those using fluid milk secured their supply from the Q cheese plant. The majority of workers consumed milk while at work and were permitted to take milk

in their own containers for use at home. In addition, a few families residing in the immediate vicinity obtained their supply there although no members were actually employed in the plant. Table 4

SEARCH FOR SOURCE OF INFECTION
At the time of the investigation, the bulk of the milk was being utilized in the production of cheddar type cheese. Of the approximately 123,000 lbs. of

presents the attack rates experienced by consumers and non-consumers of milk from the Q plant according to the type of their association with this establishment.

Regardless of consumption of milk from the plant, the workers experienced the highest frequency of illness, 56.7 per cent being affected. Almost 22 per cent of the household contacts of these workers also were ill but those in this group consuming milk from the plant experienced symptoms approximately six times more frequently than those denying use of this milk. Only 2 individuals, or 1.7 per cent, of those having no contact with the plant and denying use of milk from this source were ill. These 2 patients had onset late in the course of the outbreak, one on April 20, and the other on April 26, and it is believed represent either secondary cases or coincidental, sporadic, sore throats unassociated with the outbreak. The 9 cases occurring among users of the milk in households in which no member was employed at the plant afford further confirmation of the hypothesis that infection was transmitted by the milk.

milk handled daily in the plant, 48,000 were received from local dairymen in 40 qt. cans and 75,000 were brought to the plant by tank truck from a receiving station in Coventryville, some thirty-five miles distant. The local product was poured into the weighing vat and flowed by gravity to a temporary storage or equalizing vat (Figure 2). The bulk of this was usually used immediately by pumping through a preheater to a separator or to the cheese-making vats. The Coventryville supply was pumped directly from the tank trucks to the holding tank and from there to the preheater and separator or to the cheese vats.

The employees drinking milk at the plant did so in the cheese room. A common dipper was used and the milk was taken either from a pipe coming from the storage tanks or directly from the cheese vats. Milk to be used outside the plant was obtained from an outlet from the temporary storage vat in the receiving part of the plant. Since the use of this milk was known to have resulted in illness and it came from that part of the plant where contamination

FIGURE 2
SCHEMATIC DIAGRAM
Q CHEESE PLANT
CANNONSVILLE, DELAWARE COUNTY

from a human source was least likely to occur, the source of infection of the milk appeared to exist prior to receipt of the milk at the plant. Moreover, since the Coventryville tank truck supply only rarely was introduced into the temporary storage vat, suspicion was directed chiefly toward the local supply reaching the plant in 40 qt. cans.

The 123,000 lbs. of milk brought to the plant daily were supplied by 356 producers and represented the output of 6,069 cows. Although the epidemiological evidence suggested that the source of infection of the milk probably existed on one of the 116 farms contributing to the supply brought directly to Cannonsville, a systematic examination was made of each of the 2,029 cans

of milk received at both of the depots. A Breed smear examination was made of samples of each of these cans. On the basis of the presence of chained streptococci or excessive numbers of leucocytes (an estimated 500,000 or more leucocytes per ml.), 73 of the 356 herds were selected for further study. Each of these 73 producing farms was subsequently visited and, in addition to careful examination of each cow in these herds, information was obtained with respect to history of teat injury among the cows, or illness or superficial infections among residents of the farm. Whenever histories of teat injury were obtained or evidence of bovine mastitis was discovered, samples of milk were taken for bacteriological examination.

A total of 150 such quarter samples of milk from cows in 55 herds were examined and from 17, or 11.3 per cent, beta hemolytic streptococci were isolated. Each of these strains was identified serologically: one was found to be Lancefield Group A, 8 Group B, and a similar number Group C. The Group A organism was further identified as Griffith Type 3, identical with the strain previously demonstrated as the cause of the outbreak.

The milk containing the Type 3 hemolytic streptococci came from a cow on a farm sending its milk directly to Cannonsville. The cow had had its right hind teat stepped on and crushed some time in late February or early March, approximately 6 weeks prior to the beginning of the outbreak. The resultant injury had been treated by the son of the owner of this particular farm, and a teat dilator and milk tube had been used repeatedly in an effort to maintain this animal in the milking line. At the time of the veterinary examination on April 23, a severe, acute mastitis was found to involve the affected quarter.

Nineteen other cows in the herd were found to be normal, and 1 proved to be suffering from a benign mastitis due to an organism other than beta hemolytic streptococcus.

Histories of recent illness were obtained from 3 of 7 members of this household including the boy who had cared for the cow's injured udder. The first person affected was the mother, who experienced a severe attack of so-called "grippe" in late March. Shortly thereafter the 14 year old daughter developed scarlet fever. The son next developed a severe sore throat with fever and swollen glands in the neck. He was sufficiently ill to spend several days in bed and to consult a physician. The dates of onset in the mother and daughter definitely preceded the outbreak. It seemed impossible to ascertain definitely the date of onset in the boy,

but he sought medical care about April 18, and he had been suffering for some time before that. It appears likely, therefore, that his onset also antedated the outbreak, and in view of his caring for the incriminated cow he seems the most probable source of the cow's infection.

Repeated throat cultures were taken from this boy's throat, and were consistently negative for hemolytic streptococci; however, the first culture was taken approximately 2 weeks after cessation of his acute symptoms. Group A beta hemolytic streptococci were isolated from the throats of both of the other persons on the farm who were ill, and upon typing were found to be Type 3.

THROAT CULTURE SURVEYS

We were curious as to the prevalence of the Type 3 hemolytic streptococcus in the community, and as to the extent to which it might be disseminated subsequently through the population. Accordingly, at the time of, and again at approximately 1 and 2 months after the outbreak, throat cultures were obtained from a large sample of the population. Persons cultured included workers in the Q plant, non-employees who consumed milk from this source, and individuals having no contact of any sort with the plant. The bacteriological findings of these surveys are presented in Table 5, and shown graphically in Figure 3.

In the first survey, at the time of the outbreak, 30 of the cases occurring among consumers of milk from the Q plant were cultured and 15, or 50 per cent, were positive for the Type 3 hemolytic streptococcus. Of 33 additional consumers of Q milk who did not become ill, 2, or 6.1 per cent, were found to be carriers of a Type 3 organism, whereas none of the 104 members of the general population who denied the use of Q milk were found to

harbor Type 3 streptococci. At the time of the second survey on May 19, the percentage of cases among Q milk consumers who still harbored the Type 3 organism had dropped to 23.8 per cent. None of the other consumers of Q milk were found to carry the Type 3 streptococcus, and again no Type 3 carrier was found among the general population denying use of Q milk. At the time of the third survey on June 30, no Type 3 streptococcus was encountered, and all three groups were essentially uniform as to the percentage of hemolytic streptococci isolated, and the

percentage of these in turn which were of Group A.

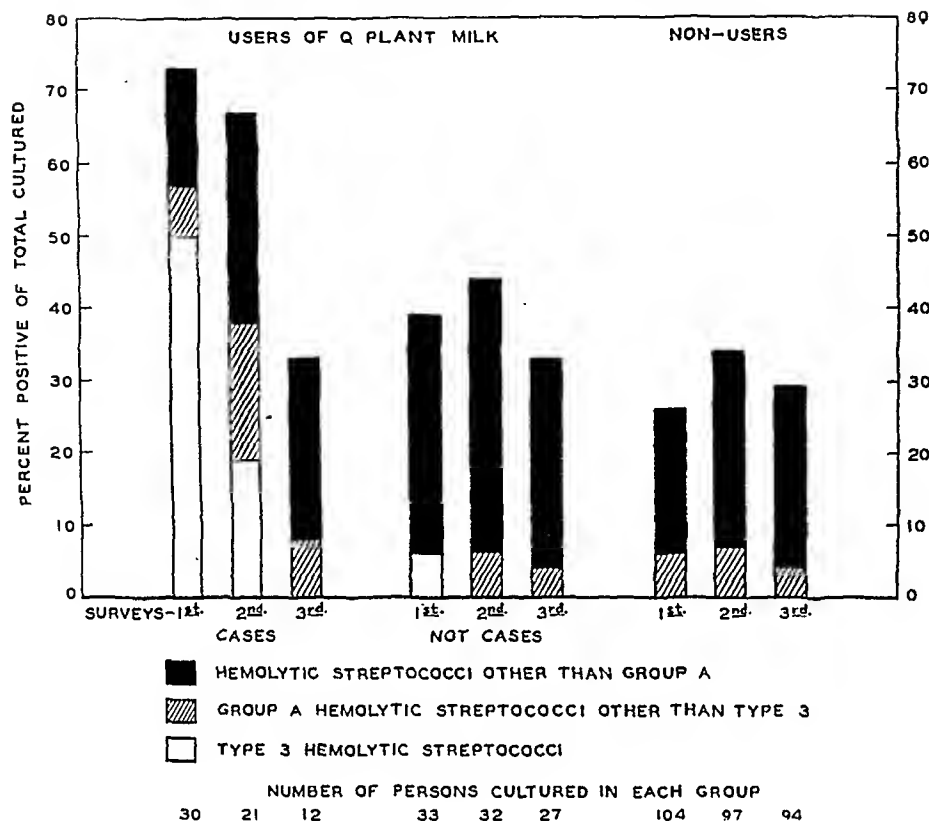

It is of interest that the frequency of nasopharyngeal carriers of all hemolytic streptococci and of Group A strains as well in the population unexposed to the Q milk remained relatively constant throughout the three surveys.

CONTROL MEASURES

As soon as preliminary evidence suggested that the milk used at or taken from the plant was the probable vehicle of infection (April 17), the distribution of this milk for drinking purposes was

FIGURE 3

THROAT CULTURE SURVEYS
HEMOLYTIC STREPTOCOCCUS THROAT INFECTIONS
CANNONVILLE, DELAWARE COUNTY

discontinued. On April 23, the cow ultimately incriminated was segregated and its milk discarded. On April 28, results of typing the hemolytic streptococcus isolated from samples of milk from this cow were available and indicated that it was the cow probably responsible for the outbreak. It was slaughtered on May 8. When udder tissue obtained at autopsy was submitted for bacteriological examination, Type 3 organisms were again recovered.

As previously stated, the principal product of the Q plant was cheddar type cheese and it was known that this cheese was being purchased by a large dealer for possible shipment to England. All cheese processed and stored in the plant between April 5, the date of last shipment, and April 22, when pasteurization of milk was begun, was embar-

goed. Samples were taken from cheese processed on each day during the interval and although large numbers of beta hemolytic streptococci were readily recovered from them, none of the many strains studied proved to be members of Lancefield's Group A. Because it was impossible, nevertheless, to state that strains of hemolytic streptococci pathogenic for man were not present in the cheese, it was treated by a process in which it was heated to a temperature of over 170° F. for several minutes, insuring destruction of any pathogenic microorganisms which might be present.

SUMMARY

An attempt has been made to determine the Griffith type of hemolytic streptococci isolated in nine milk-borne outbreaks of hemolytic streptococcus

throat infections in New York State from 1935 to 1942. A different type has been encountered in each outbreak with the exception of three outbreaks due to Type 3.

The epidemiological study of a recent outbreak of 44 cases of Type 3 hemolytic streptococcus throat infection occurring in a small rural community is described in detail. The infection was found to be transmitted by raw milk secured at a local cheese plant.

Although the cheese plant handled milk representing the output of 6,069 cows, it is believed that the cow responsible for the outbreak was located by means of Breed smear examination of cans of milk received at the plant, and subsequent veterinary and bacteriological follow-up of suspected herds.

On the involved farm it was found that prior to the outbreak there had been one case each of scarlet fever, sore throat, and so-called "grippe." The suspected cow had suffered a teat injury, followed by development of acute mastitis upon manipulation of the injured part by the person with the sore throat. Hemolytic streptococci obtained from the throats of people on the farm and from udder tissue secured from the cow at autopsy also were found to be Type 3.

Three throat culture surveys were made in the community, the first at the time of the outbreak, the second a month later, and the third approximately two months after the outbreak.

In the first survey, Type 3 hemolytic streptococci were found only in throats of consumers of milk from the incriminated cheese plant. The per cent infected with this type was less in the second survey, and in the third survey

no Type 3 hemolytic streptococcus was isolated.

To prevent any possibility of transmission of the infection through the cheese, that produced during the outbreak period was embargoed and released only after being reprocessed by a method involving heating the product above 170° F. for several minutes.

ACKNOWLEDGEMENTS—The authors wish to acknowledge their indebtedness to Drs. Stafford M. Wheeler, Rebecca C. Lancefield, Ernest L. Stebbins, and Mrs. Anna Cheskis Kling, for typing the hemolytic streptococci isolated in the various outbreaks; to Dr. Robert F. Korn and the public health nurses who assisted in the Cannonsville throat culture surveys; to members of the staff of the Bureau of Milk Sanitation who participated in the search for the incriminated cow; and to the Diagnostic Laboratories of the Division of Laboratories and Research for the original isolations of the Group A hemolytic streptococci.

Changes in the Bacterial Cell Brought about by the Action of Germicides and Antibacterial Substances as Demonstrated by the Electron Microscope*

STUART MUDD, M.D., F.A.P.H.A.

Professor of Bacteriology, School of Medicine, University of Pennsylvania, Philadelphia, Pa.

THE electron microscope is giving us new insight into fine structure in a great variety of fields. In bacteriology it is yielding an altogether clearer picture of the normal morphology of the bacterial cell. The present paper is submitted as evidence that the electron microscope is capable also of revealing structural changes brought about by antibacterial agents, and thus contributing to an understanding of the mechanism of action of such agents. Three special cases will be cited: (1) the action of simple salts of heavy metals, (2) the action of flagellar and somatic agglutinins on *Eberthella typhosa*, (3) the pneumococcal capsular swelling reaction.

Electron pictures of bacteria after brief exposure to salts of silver, lead, mercury and nickel have shown the bacterial inner protoplasm, but not the cell-walls, to be selectively darkened; shrinkage, coagulation, or escape of protoplasm from the injured cells may result and be recorded in the electron micrographs.¹ To what extent more complex chemical germicides and antibiotic substances will produce struc-

tural changes which can be recorded by electron micrography is a question for future investigation.

Electron pictures have been taken of cells of *Eberthella typhosa* exposed to homologous rabbit antiserum.^{2, 3} Specific combination with flagellar and somatic antibodies results in the formation of antibody films on the surfaces of the bacterial flagella and cell walls. The thickness of these films may increase with time of exposure to antiserum and with concentration of antiserum. Measurement of the thickness of the films deposited under various conditions are compatible with their interpretation as monomolecular films in which an ellipsoidal antibody-molecule^{4, 5} is oriented with its long axis either approximately parallel to or approximately perpendicular to the plane of the antigenic surface, depending upon concentration and other experimental conditions; however, the alternative possibility that the observed change in thickness of deposited film with antibody concentration may be due to secondary adsorption of nonspecific protein from the antiserum upon the primary antigen-antibody complex, has not thus far been excluded.

Electron micrographs of the capsular swelling of pneumococci after exposure

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

to homologous rabbit antiserum⁶ reveal a phenomenon quite different from those cited above. The increase of the capsule in thickness amounts to 2,000 Å or more, or many times the long diameter of the globulin molecule. The polysaccharide of the pneumococcal capsule is described as composed of thread-like molecules.⁷ The electron pictures are compatible with the interpretation that these molecules form a gel into whose interstices the antiserum molecules penetrate; the capsule increases in size and density in consequence of this impregnation.

The electron micrographs were taken by Dr. T. F. Anderson at the RCA Research Laboratories at Camden, N. J., and by F. Heinmetz at the Johnson Foundation for Medical Physics, the University of Pennsylvania.

SUMMARY

The electron microscope has revealed structural changes in bacteria dependent upon, (a) penetration of heavy metal ions or molecules into the bacterial cell and interaction with the inner bacterial protoplasm; (b) the formation of

surface films of antibody upon bacterial flagella and cell-walls; the thickness of these films is compatible with their being monomolecular, but this need not necessarily be the correct interpretation; (c) the impregnation of a capsule outside the bacterial cell-wall, a great increase in size and density resulting. The electron microscope is thus shown to be a new analytical tool for investigating the mode of action of at least some germicidal and antibacterial substances.

1943 Victory Book Campaign

The 1943 Victory Book Campaign is under way and will continue until March 5. The slogan in this year's drive for books for the armed forces is "Any book you really want to keep is a good one to give." Fiction, adventure, western and detective stories are asked for and technical books published since

1935 in the fields of architecture, aeronautics, chemistry, drawing, machine mechanics and design, mathematics, mechanical drawing, meteorology, military science, navigation, photography, physics, radio, shop mechanics, etc.

Support the Victory Book Campaign in your neighborhood.

Epidemiological and Experimental Observations on the Possible Significance of Rodents in a Suburban Epidemic of Poliomyelitis*

CLAUS W. JUNGEBLUT, M.D., AND GILBERT DALLDORF, M.D.

Department of Bacteriology, College of Physicians and Surgeons, Columbia University, New York, and the Division of Laboratories, Grasslands Hospital, Valhalla, N. Y.

IT is the purpose of this communication to record briefly preliminary observations bearing (a) on the recovery of a rodent-paralyzing virus from house mice collected in an endemic area of human poliomyelitis, and (b) on the apparent transfer of poliomyelitis virus to rodents from one of the human cases involved in this epidemic. Since the two sets of observations were made in the course of the same epidemic and the results serve to supplement each other, the pertinent data are here reported together.

I. RECOVERY OF A RODENT-PARALYZING VIRUS FROM HOUSE MICE IN ASSOCIATION WITH A LOCALIZED OUTBREAK OF HUMAN POLIOMYELITIS

Within a sharply circumscribed half square mile area in White Plains, Westchester County, N. Y., bounded by the Bronx River and a tributary brook, 5 cases of poliomyelitis occurred in the fall of 1942. The cases followed each other in rapid sequence between the

end of September and the beginning of October. They were the only cases of this disease reported in the entire city for the current year, though 2 cases of poliomyelitis had been reported in this locality during the previous year. The epidemic involved 2 adults and 3 children, all of whom were treated at the Grasslands Hospital, Valhalla, N. Y. Two patients died of bulbar paralysis and 3 recovered with extensive peripheral paralyses. Post-mortem examination of both fatal cases revealed severe and typical lesions in the cord and medulla.

In searching for a possible extra-human local source of contagion among rodents, a dead gray house mouse was discovered in the basement of the home of one of the fatal cases (M.M.), shortly after the patient's admission to the hospital; the animal had obviously been dead for only a short time. A second gray house mouse was trapped in this basement on the same day. Additional house mice, dead or alive, were later collected in other parts of the epidemic area. The brains of all mice were removed and, after storage in

* Aided by grants from the Philip Hanson Hiss, Jr. Memorial Fund, the Warner Institute for Therapeutic Research and anonymous donors.

glycerin for a few days, failed to cause any growth upon inoculation of ordinary bacteriological media. Saline suspensions (10 per cent) were prepared from these mouse brains and injected intracerebrally into albino mice. Definite symptoms were observed in some albino mice following injection with brain material from 3 different house mice, *i.e.*, the dead mouse and the trapped mouse found in the home in which one of the fatal cases had occurred (M.M.), and another house mouse trapped in the neighborhood.

The symptoms appeared after an incubation period of from 5 to 14 days and were characterized by ruffled fur, excitement, strong tremors, nervous movements of the forepaws, and occasional convulsions with respiratory failure. In some mice these initial symptoms progressed to paresis of both front and hind legs and terminated in death; in others, the symptoms were of a transitory character and the animals recovered. This syndrome was further transmissible in albino mice by intracerebral but not by intraperitoneal transfer of 10 per cent brain and cord suspensions from the affected mice.

While all lines of transmission originating from trapped healthy house mice came to an abrupt end after one or two laboratory passages, transmission of the infectious agent recovered from the dead house mouse has been maintained, so far, over twelve serial passages in albino mice. During the early passages the ratio between symptomless survival, convalescence, or death varied greatly from generation to generation. With subsequent passages the incubation period shortened and the described nervous symptoms became more pronounced, resulting in death of most of the injected animals and frequently in complete flaccid paralysis of one or more extremities. With later passages, mice could also be infected by the intraperitoneal route. Intra-

cerebral injection of passage-mouse brains into rabbits, guinea pigs, or rhesus monkeys failed to produce any symptoms; however, transfer to one cotton rat and two hamsters succeeded with the third and ninth mouse brain passage, respectively, leading to prostrating paralysis in the injected rodents. Sterility tests of several mouse passage brains showed them to be free from microorganisms cultivable on ordinary bacteriological media. On the other hand, the infectious agent passed easily through a Seitz filter.

Neutralization tests were carried out with later mouse brain passages by injecting young albino mice intracerebrally with mixtures of 10 per cent virus suspensions and various sera. The results of repeated tests indicated that the serum from 2 of the 3 convalescent patients neutralized virus to an appreciable extent (90 per cent survival among the injected mice), whereas neutralization was less marked with the serum from one of these patients collected during the early stages of the disease (60 per cent survival). Definite neutralization was also obtained with normal adult mouse serum (90 per cent survival), but not with normal rabbit serum (45 per cent survival). Pathological examination of mice which presented the fully developed paralytic disease showed extensive destruction of the anterior horns in various levels of the spinal cord, recalling the picture of "rodent poliomyelitis." In other words, the lesions were generally similar to those observed in mice suffering from Theiler's disease,¹ or in mice paralyzed by infection with either the mouse-adapted Lansing,² or the SK³ murine strains of human poliomyelitis virus.

The exact nature of this virus is not known at present. In view of its relatively low pathogenicity for albino mice, it has not been possible accurately to titrate potency, determine limits of

filterability, study various routes of invasion, investigate the range of susceptible hosts, or carry out more extensive neutralization tests. However, the filterability of the infectious agent, together with the symptomatology and pathology of the disease which it produces in albino mice, may be taken as suggestive evidence that we are dealing with a virus of the poliomyelitis group, perhaps identical with or related to the FA strain of Theiler's virus of "spontaneous mouse encephalomyelitis."⁴ This conclusion would be strengthened by the fact that a small group of mice which had survived this virus infection resisted intraperitoneal reinfection with a standard strain (GD VII) of Theiler's virus, whereas normal control mice developed paralysis. It should be noted, however, in this connection that heretofore Theiler's virus has not been encountered in healthy gray house or field mice (brain or intestines) trapped at a distance from the laboratory.⁵ Final identification of the described infectious agent and the relationship, if any, which may exist between its local carriage by house mice and the synchronous outbreak of human poliomyelitis are problems which are at present under investigation.

II. ISOLATION OF A RODENT-PARALYZING VIRUS BY PASSAGE OF HUMAN POLIOMYELITIS VIRUS TO SYRIAN HAMSTERS, EASTERN COTTON RATS AND ALBINO MICE

Attempts to corroborate the clinical and pathological diagnosis of poliomyelitis in the 2 fatal cases referred to above were made by tests in rhesus monkeys. Intracerebral injection of a monkey with brain and cord material from one of the fatal cases (T.D.) failed to produce any symptoms. However, prostrating paralysis, with typical cord lesions, occurred in another monkey following intracerebral injection with a suspension from cord and medulla of

the second fatal case (M.M.). Intracerebral transfer of this monkey cord to another monkey failed to transmit paralysis but caused death in a hamster on the 20th day after injection. At the same time the original human material was also injected intracerebrally into other laboratory animals, i.e., 1 rabbit, 3 guinea pigs, 19 albino mice, 2 cotton rats, and 1 hamster. None of the injected animals showed any definite signs of disease, except for the hamster, which appeared sick on the 18th day after injection and was found dead the next morning. Intracerebral transfer of this hamster's brain to another hamster caused in the latter animal complete flaccid paralysis of both hind legs within 5 days. Further intracerebral passage of the paralyzed hamster's brain to 2 new hamsters, 2 cotton rats, 5 albino mice, 1 rabbit, and 1 rhesus monkey was followed by prostrating paralysis, within 2 to 3 days, in all injected small rodents. The monkey developed a transient fever but remained free from recognizable paralysis; no symptoms were observed in the rabbit. From this point it was possible to transmit the disease serially through passages of hamsters and mice, using both intracerebral and intraperitoneal routes of injection.

The infectious agent proved filterable through Seitz filters; it passed readily through graded collodion membranes of 50 mu APD and with considerable difficulty through membranes of 26 mu APD, but was completely retained by membranes of 10 mu APD. The probable size of the virus particle may therefore be assumed to lie in the neighborhood of 10 mu. Of special interest is the enormous potency and invasiveness of this virus. In both intracerebral and intraperitoneal tests dilutions between 10^{-3} and 10^{-5} were capable of inducing paralysis in hamsters, while dilutions as high as 10^{-11} sufficed to paralyze albino mice, by either intracerebral or intra-

peritoneal injection, within an incubation period of from 24 hours to 5 days.

Pathological examination of paralyzed hamsters and albino mice revealed the presence of typical and severe poliomyelitic lesions in the entire central nervous system. Neutralization tests were carried out by injecting albino mice intraperitoneally with mixtures of mouse passage virus and various sera. The results of repeated tests may be summarized as follows: A high degree of virus neutralization was obtained with a rabbit antiserum against Theiler's virus (1 million paralytic doses) and with a rabbit antiserum against SK murine virus (10,000 paralytic doses)⁶; a moderate or slight degree of virus neutralization occurred with an antipoliomyelitis (monkey virus) hyperimmune horse serum (100 paralytic doses) and with three convalescent sera collected from surviving patients in this epidemic (10 paralytic doses). Control sera which failed to neutralize the virus at the indicated levels were normal horse, rabbit, and hamster serum.

From what has been said before, it is clear that the cord and medulla of the fatal case (M.M.), upon direct inoculation, was capable of causing paralysis in one rhesus monkey only. It also appears that the human material was primarily non-pathogenic for cotton rats and albino mice, but that intermediary hamster passage had evidently brought about some change in the virus which made it possible subsequently to maintain multiple paralytic passages in several species of rodents, including hamsters, cotton rats, and albino mice.

The above facts, while suggesting that a direct transfer of poliomyelitis virus was obtained from man to hamster—with further transfer from hamster to cotton rats and white mice—are ad-

mittedly insufficient actually to prove such transmission. The possibility that accidental contamination may have occurred with a latent virus, or with a virus carried in the laboratory, cannot be ignored. However, the circumstances under which these observations were made and the trend of the available data would tend to minimize the chances for such a contamination. It is hoped that further work, which is in progress, will help to clarify not only this problem but make it possible to pass final judgment on the identity or non-identity of the two paralyzing viruses isolated from man and mouse in the course of this epidemic.

CONCLUSIONS

A rodent-pathogenic virus which paralyzes albino mice, cotton rats, and hamsters was isolated from the brain of a house mouse found dead in the home of a fatal case of human poliomyelitis. Another rodent-pathogenic virus capable of inducing paralysis in albino mice, cotton rats, and hamsters was isolated from the brain stem of this fatal case. The two viruses, when passaged in albino mice, are similar in that both are completely inactivated by antisera against Theiler's virus of mouse encephalomyelitis and show some neutralization with convalescent sera from patients involved in this epidemic. They differ however markedly in virulence for albino mice in that the human virus is much more potent than the mouse virus.

GENITOINFECTIONOUS DISEASE AND EMPLOYMENT

THE above heading is the title of an article which appeared in the October, 1942, issue of the *Bulletin of Genitoinfectious Diseases*, published by The Massachusetts Society for Social Hygiene, Inc. The author is Dr. N. A. Nelson, of The Johns Hopkins University, School of Hygiene and Public Health.

The attention of *Journal* readers is earnestly called to this paper, for here Dr. Nelson attempts to bring a modicum of order out of the confusion of measures instituted in one direction or another, by one agency or another, for the control of venereal diseases. He throws into startling relief the fact that we have made somewhat of an unholy hash of such measures, in that persons with positive sera and no other evidence of syphilis, are in many instances assumed to be in a communicable stage, and on this basis it is common practice to exclude them from employment.

To undertake further to paraphrase and condense the article in question would be unwise, for to get its full savor one must read it as a whole. However, two passages will give an idea of the incisiveness of Dr. Nelson's thinking, and, it is hoped, will encourage *Journal* readers to go back to the original. The author says:

"It has been easy to persuade industry to do blood testing because industry thought it could see something of advantage to itself in the procedure. The health department wanted to find infection and treat it, but instead of saying so, it has sold the idea to industry as a measure for the protection of industry. It has dwelt so long and loudly upon the dangers of genitoinfectious disease that employers have concluded that the only safe way out is to exclude the infected from employment altogether.

"There is no relationship whatever between the positivity or negativity of a blood test and the infectiousness of syphilis. A person with an early primary lesion, or one with an inadequately treated and potentially infectious early syphilis, may have a negative test. The majority of detectable infections to be found in any community, at any given time, are non-communicable by virtue of their age, or as the result of treatment; yet most of them will produce positive tests. Thus, the argument that a positive test should serve to exclude a person from employment, because syphilis is a communicable disease, is fallacious."

Copies of the publication in which Dr. Nelson's article appears may be obtained from the Massachusetts Department of Public Health, Room 545, State

House, Boston. We are glad to act as publicity agent in this instance, for only through such approaches as this sane one of Dr. Nelson's shall we be able to disentangle some of the knots that have been tied by emotion, wishful thinking, and opportunism.

A SOUR OBSERVATION ON THE LANHAM ACT

FEDERAL legislation relating to the public health moves somewhat fast and confusingly in these days of stress and change. As to that bit of it known as the Lanham Act, we find that we must keep our editorial fingers crossed. The Act provides that federal grants may be made for the purpose of increasing or providing public works in those areas where, because of war activities, similar existing facilities are inadequate. Undoubtedly, many localities will be benefited through this Act and, from a broad national standpoint, it is quite logical and only fair that the federal government bear a part of the financial burden carried in various localities when that burden is heavy because of national interests and activities. There is, however, in this Act a disquieting feature in so far as federal public health administration is concerned. Thus, though the intent of the Act in its relation to health is stated specifically to be the provision of facilities and public works (water and sewerage system, garbage disposal, recreational facilities, hospitals, etc.), there seems danger that the operation of a local public health service, voluntary or official, may be interpreted as coming within the definition of "public works." It is to be hoped, and sincerely hoped, that those responsible for the administration of the public health aspects of the Act will not go seriously into the business of subsidizing health services. The need for public health facilities in the areas in question is sufficient to absorb all the funds available and, in the provision of such facilities, the administrators of the Lanham Act have the ample experience of the Work Projects Administration upon which to draw. They do not know, nor are they now likely to be able to employ persons who know, either the relative seriousness of public health problems or the comparative values of local public health practices. Further, for the Lanham Act administrators to enter into subsidy of local health services would put into this field still another national administrative unit with money to spend and terms to lay down. The situation is confused enough as it is, but to introduce into it a new federal group which would deal with the thousands of local health agencies in the United States, is likely to create far more chaos than benefits.

Many will have forgotten that we went through a somewhat similar mushroom growth of federal health agencies in World War I. The situation became so distressing that Mr. Wilson finally put an end to it by a Presidential order, placing under the U. S. Public Health Service all federal public health activities except in relation to the Army and Navy. It is, of course, too much to hope that Mr. McNutt would be willing to put all the Federal Security Agency's health activities under the Service, or that the President might on a major scale similarly pull together the public health activities scattered throughout the federal government.

It is not a bad idea, at that.

BOOKS AND REPORTS

Introduction to Parasitology—By A. S. Pearse. Baltimore: Thomas, 1942. 357 pp. Price, \$3.75.

In the preface, the author of this book states that it is intended primarily for college students. This book, therefore, represents no major contribution to the excellent texts already available on the subject of medical parasitology. With this in mind one cannot be too critical of deficiencies in the text, namely, in relation to the handling of the clinical and therapeutic aspects of human parasitic diseases. On the whole, it is felt that for medical students, public health men, and practitioners, this book is not to be recommended as a practical text or source book on the subjects of diseases produced by animal parasites. It would seem worth while if one were getting a text, to invest the extra few dollars if necessary and obtain one of the more recent books especially written for medical men.

For college students, the material in Pearse's text seems well presented and profusely illustrated by fairly good drawings.

HARRY MOST

A Venture in Public Health Integration—*The 1941 Health Educational Conference of the New York Academy of Medicine*. New York: Columbia University Press, 1942. 56 pp. Price, \$1.00.

Because this brief book needs so badly to be read by public health administrators and by everyone among us who is in a position of power or trust, the words "health education," I suspect, were purposely omitted from the name given to these transactions. Whether or not that is the reason for choosing the provocative wording of the

title, this is no manual, handbook, or working guide for health educators. Instead it is a statesmanlike discussion of the rôles of the practising physician, the voluntary agency staff member, and the public health official in an integrated plan of adult health education.

First to be considered, is the growing significance of geriatrics in public hygiene and, with it, the opportunity and the duty of practising physicians to improve the health of the aged through lifetime personalized guidance.

After a merciless dissection of most of the faults of our present-day hodge-podge of educational effort, the second part proposes a nationally planned attack to orient objectives, to formulate state and community programs, and to direct research in content and method.

Certainly one of the most stimulating definitions of health education thus far propounded introduces the last part of the discussion. Though it is almost two pages long, when it is ended, the whole problem stands out sharp and clear before a background of fact. Whoever the belted and spurred officers may be, the slogging, sweating infantry in this war against ignorance is the local health department. It alone can fit teaching to need, can reach those whose necessity is greatest, can make education work.

Yes, every one of us needs badly to read this book.

RAYMOND S. PATTERSON

Get More Out of Life—How Troubled People Can Find Help—By Catherine Groves. Introduction by Dr. Howard W. Odum. New York: Association Press, 1941. 136 pp. Price, \$1.25.

Counsellors as well as persons in need

of counsel will be helped by reading this interpretation of one of the most recent and least understood fields of social service.

Out of a background of training and practical experience, the author interprets clearly and concisely why people can be helped by discussing personal problems with someone who may be able to get a perspective and who is neither a friend nor a relative. Practical illustrations are skillfully used to clarify various problems in human relationships which may arise.

Emphasis is placed upon the need of professional skill in counselling, although backgrounds of training may vary. Physicians, psychiatrists, educators, clergymen, social workers, and nurses all have opportunities for helping persons in trouble. They will find it worth while to read this excellent analysis of how to help people to help themselves.

Stress is placed upon the limitations of the counselling field. A good counsellor knows when other skills are needed and does not hesitate to refer clients to a specialist when indicated.

A section of the book deals with the danger of charlatanism and advises persons in trouble how to find the service needed.

VALERIA HOPKINS PARKER

The Amateur Scientist. Science as a Hobby (*Two Appendices*)—By *W. Stephen Thomas*. New York: Norton, 1942. 291 pp. Price, \$3.00.

As pointed out in the Foreword, Benjamin Franklin, who founded the American Philosophical Society in 1780, was one of the greatest of amateur scientists, and Philadelphia, in which he spent much of his life, has been noted for the cultivation of science among amateurs. It is fitting therefore that the society which he founded and which has its home in Philadelphia should sponsor a Committee on Educa-

tion and Participation in Science. The present book is based largely on the researches and findings of that committee, and the writer, secretary of the committee for three years, was Director of Education at the Academy of Natural Sciences, so that no better atmosphere could have been found for such a work.

The book begins with a study of the characteristics of amateur scientists in general and their motives for taking up as a hobby some branch of science, which, as the book shows, vary from the practical to the abstruse. Among amateur scientists, many of whom have made notable contributions, can be found all classes, from professional men in law and medicine, to brick masons, postmen, printers, office workers, etc. An Appendix gives the occupations of 727 men and women in the Philadelphia area who are interested in science as amateurs. These people represent 134 occupations classed under five headings, Professional; Business; Skilled and Semiskilled, Technical and Nontechnical; Service; and Miscellaneous. There are detailed studies of four sample subjects in which some 500 amateur scientists have taken part: Blooming Dates of Plants, Climatology and Tree Rings, Radio Ionosphere, and Report on the Project in Zoology.

The fact that a body such as the American Philosophical Society has considered it worth while to investigate the subject under a committee chosen for the special aptitude of its members insures us that the estimate of the importance and value of the amateur scientists is fully justified. Indeed the project was proposed by the President of the Carnegie Corporation, and the offer made to supply financial support for the study of adult education in science in the Philadelphia area if the Philosophical Society would undertake it. Another very great advantage is to the amateur scientists themselves,

strikingly expressed as early as 1859, by Charles Kingsley, who wrote:

"I have known, again and again, working men, who in the midst of smoky cities, have kept their bodies, their minds, and their hearts healthy and pure by going out into the country at odd hours and making collections of plants, fossils, insects, birds, or some other objects in natural history."

A wide range of readers will find this book of interest and value. The printing and make-up are excellent and the illustrations are largely reproductions of photographs showing direct from life features of the studies which were made.

MAZÛCK P. RAVENEL

Tables of Food Values—By Alice V. Bradley. (rev. ed.) Peoria, Ill.: Manual Arts Press, 1942. 224 pp. Price, \$3.50.

The revised edition of *Tables of Food Values* presents conveniently arranged data on composition of foods as eaten. Some such handbook is a "must" for any public health worker who has occasion to plan or evaluate diets on the basis of the daily allowances for specific nutrients recommended by the Committee on Foods and Nutrition of the National Research Council.

The nutritive values of a very large number of foods, raw, cooked, and combined in dishes, are given in two complete sets of tables. The tables in Part I, intended for rough estimation of the nutritive value of individual foods and typical diets, give values for average servings. The tables in Part II, suggested for use in computing the value of weighed diets, are based on 100 gram portions. In both sets of tables foods are arranged in 27 groups, starting with Beverages and ending with vegetables. The tables are unusually comprehensive, including many less common foods often omitted from such compilations.

The typography and the format of the tables are excellent. Reprinting the kind of food at the extreme right of each double page of figures is an especially happy device. The tables might be simpler and more useful if all data were expressed only in the same quantitative units used in the recommended dietary allowances of the National Research Council.

Anyone who compares the data for given foods in the various handbooks now in circulation will appreciate that most values are approximations to be used in rough estimates and broad comparisons. For such purposes it is probably wise to take all values from a single handbook and so to avoid adding still another variable to an inescapably long list. Before deciding which handbook to abide by, public health workers may well examine the revised edition of *Tables of Food Values*.

MARJORIE M. HESELTINE

A Handbook of Allergy for Students and Practitioners — By Wyndham B. Blanton, M.A., M.D., Litt.D. Springfield, Ill.: Thomas, 1942. 190 pp. Price, \$3.00.

Blanton's *Handbook of Allergy* should fulfil well the purpose for which it is primarily intended. It is a synopsis-type work, for use by the undergraduate student, to be supplemented by personal instruction. It should also serve as a handy orientation volume for graduates who wish to become acquainted with the general subject of allergy. The discussion of treatment, both specific and symptomatic, is too abbreviated for the volume to serve adequately as a therapeutic reference aid. It is hoped that in the next edition treatment will receive more detailed discussion. When used as an undergraduate text, this becomes less of a problem since the student gains his therapeutic experience in the ward and clinic.

WARREN T. VAUGHAN

Ornithologists of the United States Army Medical Corps. (*Publications of the Institute of the History of Medicine, The Johns Hopkins University. First Series: Monographs, Volume I*)—By Edgar Erskine Hume. Baltimore: Johns Hopkins Press, 1942. 583 pp. Price, \$5.00.

The Medical Corps of the Army has given us many things of great scientific as well as practical value. We need mention only the greatest medical library in the world, the Army Medical School, "America's oldest school of preventive medicine," and the discovery of the transmission and prevention of yellow fever. Here we are told of the contributions made by Army medical officers to other branches of natural science, especially the study of the birds of the American continent.

We have been fortunate in the fact that the Surgeons General have, practically without exception, fostered scientific studies on the part of the officers, and many have purposely made assignments to foster scientific work of various types. This applies also to officers in command, such as General Leonard Wood, who was greatly interested in natural history and had much to do with the bird studies of many of the officers under him. The record is in striking contrast to some things which have happened elsewhere—for example, the near tragedy of repeated official interference with the work of Ronald Ross on malaria.

As far as the particular subject with which this book is concerned, it was fortunate that the Surgeons General as well as the Army medical officers under them between 1850 and 1860 were largely inspired by Baird of the Smithsonian Institution, created by Congress in 1846. Advantage was taken of railway and other expeditions—so much of the record of the ornithological activities of the Army medical officers

have been preserved in such reports as those of the Pacific Railroad Surveys. There was from the beginning a happy union between the Medical Corps of the Army and the Smithsonian Institution, fostered by the marriage of Professor Baird, Assistant Secretary, to the daughter of Colonel Sylvanus Churchill, Inspector General of the Army. The Smithsonian Institution has profited tremendously and in that famous Museum there are to be found the fruits of the "extracurricular" labors and studies of the members of the Army Medical Corps.

The book contains sketches of 36 Army medical officers who have contributed to our knowledge of the birds of America, a number of whom did not confine themselves to birds, but covered other valuable features of natural history. Many specimens of mammals, reptiles, fishes, and other groups were sent to the National Museum in Washington, where they are now.

There was a method in the assignment of young officers to our western country where the Army was taking part in the "winning of the West." Many articles were written and many specimens collected during this development, and it is notable that the first draft of the great book by Surgeon Elliott Coues, *Key to North American Birds*, was written at Fort McHenry.

It is interesting to note also that a number of these army surgeons showed other talents and skills. The frontispiece of this volume, for example, is the Blue-headed fly catcher, printed from the original plate drawn and engraved on copper by Dr. Anderson. Others have written excellent poetry; some have painted.

There are many more things which one would like to say about this book. It contains much history of the period when the West was being opened up and the first railroads were being pushed

across the continent. Of the 36 Army doctors mentioned, there is not one whose life does not possess much of interest scientifically as well as of value historically.

The book contains 109 illustrations. There is at least one photograph of each individual, and for some of them there are several. There are pictures of many of the famous frontier posts of the Army and a number of ornithological specimens. There is a short "Conclusion" summing up the work of Army medical officers, the names of most of whom are familiar to the world, men who have placed the people of all countries in their debt. An excellent index adds to its value.

The book is beautifully made on glazed paper, and is a masterpiece of the printer's art. We must give full credit to the author, Colonel Edgar Erskine Hume, for an enormous piece of work competently done. He has placed all lovers of natural history and scientific men in general under obligation to him, and he himself has shown a large degree of that versatile ability for which so many medical officers of the Army have been noted.

MAZYCK P. RAVENEL

Health Facts for College Students: a Textbook of Individual and Community Health—By Maude Lee Etheredge. (4th ed.) Philadelphia: Saunders, 1942. 364 pp. Price, \$2.25.

The fourth edition of *Health Facts for College Students* impresses this writer, first as being well written for and about college students, with a clear and sympathetic understanding of their problems; second, hygiene for this group is well discussed but with too little explanation. To illustrate, with regard to nutrition, the existence of body types is noted but the fact that these types are often mistakenly dieted to have them conform to the standard height-weight tables is not explained.

Students will benefit from having received health education in some form or other before entrance to college but to keep their interest they must be stimulated by a real academic challenge. Supplemented by more detail and explanation, this book can play a definite part as a text in a course in college hygiene.

GRETTA WREN

Chemistry of Insecticides and Fungicides—By Donald E. H. Frear. New York: Van Nostrand, 1942. 300 pp. Price, \$4.00.

This is an account of the chemical substances used primarily in agriculture and to some extent in industry as a protection against the attacks of insects and fungi upon plants and their products. It does not cover the protection of animals and their products from attacks by these organisms. It is of value and interest to public health because of the use of preparations of arsenic, fluorine, thallium, and other toxic substances as protective sprays upon fruits and vegetables and as poisons for destructive rodents. Detailed directions are given for the various chemical processes used in testing for the presence and amounts of these toxic substances.

Wood preservation by creosote and other organic materials is referred to only casually. The widespread use of arsenicals by fruit growers and gardeners, and their removal by uncontrolled washing devices, if at all, creates a potential health hazard which rarely comes to medical or public attention, much less to critical testing by competent public health authorities. The ephemeral nature of the results upon the individual consumer makes detection and prevention doubly difficult.

More inspection and analysis by health authorities is imperative to determine the sources, extent, and nature of these hazards. This book is a help to these ends.

CHARLES A. KOFOID

Eat What You Want—A Sensible Guide to Good Health through Good Eating—*By W. W. Bauer, M.D., and F. M. Bauer. New York: Greenberg, 1942. 263 pp. Price, \$2.00.*

This volume contains a surprising amount of exact nutrition information, presented in a popular style by a trained publicist. It attempts to make the acquisition of this knowledge as painless as possible and succeeds very well if the reader be above average in intelligence, and does not object to a loquacious rather patronizing style of writing. The book is quite evidently addressed to the economic group that can afford and can purchase satisfactory diets, though Chapter VIII comes to grips with the problem of low-cost meals. Such practical problems as meals at restaurants, drug store lunches, meals on trains, feeding children enroute are analyzed, and a plea is inserted for food purveyors to make it easier to get a good meal than to get a bad one. The box lunch for workmen or school children is presented in the light of its true importance as the source of one-third of the day's nutritional requirements.

The tabular material of the book merits particular attention, *e.g.*, The Table of Standard Weights for Men, on pages 64–65, A Table of Median Calorie Values of Common Foods, pages 76–81, Recommended Daily Allowances of Specific Nutrients, page 85, Marketing Lists (Low Cost and Liberal), pages 184–187, and the many menu lists throughout the book.

Chapter VI on vitamins contains much good advice, *e.g.*, "The necessary vitamins can and should be obtained by judicious selection and preparation of foods"; "nothing is to be gained by taking capsules which furnish vitamins in large excess"; "a wisely chosen diet can furnish all the necessary vitamins." Chapter VII really

gets down to practical cookery and contains 35 pages of forms and information for survey of personal diets. The debunking of food fads in Chapter 10 can be helpful to many misguided enthusiasts.

Misstatements of fact in the book are rare. Such a one as the recommendation of cooked prunes as a source of vitamin C at breakfast should be taken with extreme caution. On the whole the book can serve as a guide to individual eating, or as a sourcebook of information for public presentation. The catch phrase title should not mislead the unwary about the simplicity of the material presented.

D. F. MILAM

We Fight Syphilis and Gonorrhea
—*Prepared by Adult Education Materials Project, in coöperation with the Chicago Health Department—Syphilis and Gonorrhea Section. Chicago: University of Chicago, 1942. Teachers Book—44 pp.; Book I—19 pp.; Book II—31 pp.; Book III—44 pp.*

How to reach all levels of education and reading ability with the facts about syphilis and gonorrhea has always been a problem for the social hygiene educator. It is especially difficult to reach the adult who may be unable to read in any language or who may read only in a foreign language. The Adult Education Materials Project of the Work Projects Administration at the University of Chicago, has hit on a double-barreled solution—teach these people to read and at the same time give them the facts about syphilis and gonorrhea.

We Fight Syphilis and Gonorrhea is a series of three illustrated booklets and a *Teacher's Guide*. Books One, Two, and Three are each written at a different level of reading difficulty on the same subject, thus enabling the teacher to guide the reading of a class of varying educational training and background. Besides serving as basic texts

for the subject itself, these lessons also furnish material for the study of English—reading, pronunciation, grammar, spelling, sentence construction, and oral English.

The *Teacher's Guide* contains useful information on how to use the three lesson booklets. It includes material on class procedure, reading, spelling, and writing practice, testing the student's knowledge, and a list of suggested reading and visual aids. A wise word to the teacher warns against attempting to give personal advice. The teacher is told to direct inquiring students to clinics or physicians for detailed information or examination.

JOSEPH L. STENEK

With This Ring—By Ethel Miller Nash. New York: Association Press, 1942. 112 pp. Price, \$1.50.

In a small volume of little more than one hundred pages, Mrs. Nash has covered the life cycle from the "falling in love" period through marriage, the care and training of children, including early religious training and adolescence—necessarily each phase cannot be covered adequately. One could wish that the matter of child care and training had been left for another volume.

Mrs. Nash's suggestion that the menstrual period be utilized as a "period of meditation" will seem to some inadvisable as well as impractical. The modern woman has, in the main, learned to place little emphasis on this period. This is due, in part, to more sensible dress, consequent improvement of health, and busier and more interesting opportunities in life. The chapter on religious education will interest a limited number of parents whose point of view agrees with that of the author. Others will differ widely.

The warning concerning "war-time marriages" is timely. The author says: "Marriages contracted in wartime are not different from those contracted in

peacetime. It is rather that the difficulties of marriage are thrown into clear relief. The temptation is to reason that, because of the special circumstances, the ordinary rules of caution do not apply. Nothing could be further from the truth. Marriages should be entered into during a war emergency only after a more than ordinarily careful consideration has been given to all the elements involved. Categorical statements of a general nature are rightly suspect, but nevertheless it is possible to say that the presence of certain specific emotional and physical factors make marriage unwise in both wartime and peacetime!" Those factors are enumerated through examples of actual marriages.

VALERIA HOPKINS PARKER

Fundamentals of Psychiatry—By Edward A. Strecker, M.D. Philadelphia: Lippincott, 1942. 201 pp. Price, \$3.00.

The purpose of this book is to bring psychiatry in a "usable form to the medical student and practitioner." Its compact form "will enable the reader to obtain with a minimum of time, a workable picture of the field of psychiatry—knowledge which constantly can be interwoven with his work." These statements from the preface are well borne out by the organization of the text, which deals briefly with all parts of the subject under consideration, from historical backgrounds to present-day problems engendered by war activities.

At the present time it is particularly important for all physicians to take an interest in psychiatric matters in the light of the special investigations in psychoneuroses, and psychosomatic medicine of the past few years, during which many interrelationships with all branches of medicine and with the social sciences have been demonstrated.

There are many relatively large tomes on psychiatry, available to students and others who wish to review the subject

or to inform themselves in detail on some particular topic in mental medicine. However, there is a definite need for this volume, which is handy in size and which presents highly complex subject matter authoritatively, without becoming involved in technical or theoretical considerations; moreover it is arranged for teaching purposes in accordance with the long experience of the author who has proved its value in his teaching activities as professor at the University of Pennsylvania.

The section on war psychiatry is highly modern and presents briefly the scope of the problems confronting psychiatrists in the present emergency, summarizing the important basic conditions that should be recognized and treated.

The book should prove to be a sound, useful source of information for all workers interested in the subject. The text is illustrated by graphs and has been adequately indexed.

NOLAN D. C. LEWIS

Bacteriology for Students of Medicine and Public Health—By Einar Leifson, Ph.D. Medical Student Series, Fred C. Zapffe, Editor. New York: Hoeber, 1942. 526 pp. Price, \$5.00.

This is an attempt to present a new approach to the study of bacteriology. As expressed by the editor, the objective has been to "present what the student has time to read, and at a price he can afford to pay."

Dr. Leifson has succeeded very well in providing a streamlined text with a clear presentation of representative material drawn from the enormous field properly included under the term "Bacteriology." Five chapters are devoted to the general biology of bacteria, eight to the systematic study and classification of bacteria, and four to laboratory technic.

In addition, he has found time and

space to correlate the subject with other fields. For example, six chapters relate bacteriology to immunology and host resistance. One chapter discusses the relations of bacteriology to agriculture and industry. Other chapters discuss biostatistics, epidemiology, mycology, parasitology. Nineteen chapters deal with diseases of major importance.

In theory, such correlations are sound. In practice, they are difficult to attain to the satisfaction of all. The underlying purpose of dividing medical teaching into various branches is that the student may get more adequate and intensive instruction in these particular fields. Correlations conducted by each branch separately involve repetition which may or may not be advisable. In this particular instance the incursion into the fields of biostatistics and of clinical medicine may be debatable.

The general plan for the chapters on disease includes brief discussions of prevalence, epidemiology, diagnosis, treatment, and control. Certainly valid objections can be raised to having diagnosis and treatment of disease discussed in a course in bacteriology given to students who as yet have no clinical contacts, by instructors who carry no clinical responsibility. To illustrate, it is easy for a bacteriologist to state, "The clinical diagnosis of scarlet fever usually offers little difficulty" (page 319). The clinician, no doubt, will raise his eyebrows over that statement, because of the difficulty experienced in deciding the diagnosis of the large number of atypical cases. In the chapters on disease there occur other statements to which objection may be made. Although of minor importance they detract somewhat from the value of the book as a whole.

It is in the chapters devoted more definitely to bacteriology that the author is at his best. He presents the material clearly and concisely. Perhaps he is too concise in some instances,

but every sentence is meaningful. Moreover, he has a happy faculty of introducing explanatory material not usually available in commonly used textbooks. The student learns why stains act as they do, why differential stains of the body, capsule, flagellae, etc., are possible. Biochemical explanation of cultural characteristics is a very helpful feature. Carefully pre-

pared suggestions as to practical procedures are provided. Needed details as to culture media and animal inoculation are included. In fact, the pages are replete with information which the medical student can use with great profit. In this field, Dr. Leifson has made a definite and constructive contribution.

M. E. BARNES

BOOKS RECEIVED

INFANT AND CHILD IN THE CULTURE OF TODAY. The Guidance of Development. By Arnold Gesell and Frances L. Ilg. New York: Harper, 1943. 399 pp. Price, \$4.00.

PRACTICAL SURVEY OF CHEMISTRY AND METABOLISM OF THE SKIN. By Morris Markowitz. Philadelphia: Blakiston, 1942. 196 pp. Price, \$3.50.

THE STANDARD OF LIVING IN 1860. American Consumption Levels on the Eve of the Civil War. By Edgar W. Martin. Chicago: University of Chicago Press, 1942. 451 pp. Price, \$4.50.

SERVICES TO THE ORTHOPEDICALLY HANDICAPPED. Report of a Study made under the auspices of the Trustees of the Widener Memorial School for Crippled Children and the Board of Public Education School District of Philadelphia. Philadelphia, 1942. 115 pp.

BUILDING MORALE. By Jay B. Nash. New York: Barnes, 1942. 154 pp. Price, \$1.00.

CURRICULUM PROBLEMS IN HEALTH AND PHYSICAL EDUCATION. By Vaughn S. Blanchard. New York: Barnes, 1942. 128 pp. Price, \$1.50.

THE FOOD YOU EAT. A Practical Guide to Home Nutrition. By Samuel and Violette Glasstone. Norman: University of Oklahoma Press, 1943. 277 pp. Price, \$2.25.

COMMON EDIBLE MUSHROOMS. By Clyde M. Christensen. Minneapolis: University of Minnesota Press, 1943. 124 pp. Price, \$2.50.

REGAIN YOUR FIGURE. How to Recover the Figure after Childbirth without "Strengthening" Exercises. By Lt. Col. J. K. McConnel. Cleveland: Sherwood Press, 1939. 128 pp. Price, \$2.00.

PRINCIPLES OF MEDICAL STATISTICS. By A. Bradford Hill. 3rd ed. London: Lancet, 1942. 189 pp. Price, \$2.25.

LABORATORY MANUAL ON FUNDAMENTAL PRINCIPLES OF BACTERIOLOGY. By A. J. Salle. 2d ed. New York: McGraw-Hill, 1943. 184 pp. Price, \$1.50.

THE FREEZING PRESERVATION OF FOODS. By Donald K. Tressler and Clifford F. Evers. New York: Avi Publishing Co., 1943. 763 pp. Price \$8.00 Domestic, \$8.25 Canada and Foreign.

PROCEEDINGS OF THE NATIONAL CONFERENCE OF SOCIAL WORK. Selected Papers, Sixty-Ninth Annual Conference, New Orleans, La., May 10-15, 1942. New York: Columbia University Press, 1942. 670 pp. Price, \$5.00.

ESSENTIALS OF NUTRITION. By Henry C. Sherman and Caroline Sherman Lanford. 2d ed. New York: Macmillan, 1943. 442 pp. Price, \$3.50.

HEALTH IN THE NEWS. Highlights in the News from the Realms of Medicine and Public Health as Prepared and Presented Weekly over Radio Station WEAN in Providence, R. I., from Oct. 31, 1941, to July 29, 1942, by John E. Farrell. Rhode Island: Providence Medical Association, 1942. 113 pp.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Another Wind-blown Straw— Pulmonary tuberculosis in England increased during 1941 by 10 per cent over the prewar year, 1938–1939. In Scotland the increase is 18 per cent, and for non-respiratory forms the increases are 21 per cent and 28 per cent respectively in the two countries. Old, young and middle-aged groups were counted in the increases. In the young, tuberculous meningitis was the chief cause for the rise. The record hardly needs an inspired interpreter to read the handwriting.

ANON. Tuberculosis in War Time (An Editorial. *Pub. Health.* 56, 2:15 (Nov.), 1942.

Next Year's Babies—More and more, the nation's babies are being borne by very young women, but the proportion of these young women to all in the reproductive ages is decreasing. Absence of young husbands and marriageable young men will tend soon to decrease birth rates among these young women. Will the mothers—aged 30 or more—who have some children already, whose husbands are not subject to the draft, and who are now in a better economic position, help out to moderate the future unfavorable effect of war upon our birth rate?

ANON. Mothers Today Are Younger. *Statistical Bull.* (Met. Life Ins. Co.) 23, 11:1 (Nov.), 1942.

Outstanding Medical Achievement—Impressively reassuring is this analysis of pneumonia mortality. In five years the rate has decreased 63 per cent and the profile of the seasonal mortality curve has so flattened out in

the five year interval as to be almost unrecognizable.

ANON. Pneumonia Death Rate Lowest on Record. *Statistical Bull.* (Met. Life Ins. Co.) 23, 11:8 (Nov.), 1942.

Dangerous Enthusiasm—Animals develop pronounced pathological calcification of various organs during experimental hypervitaminosis (D) with pronounced pathologic changes in teeth and jaws. This, warns the author, should discourage excessive and indiscriminate vitamin D therapy.

BECKS, H. Dangerous Effects of Vitamin D Overdosage on Dental and Paradental Structures. *J. Am. Dent. A.* 29, 17:1947 (Nov.), 1942.

Paratyphoid A and B and Friends—There are more *Salmonella* infections than health officers generally suspect. Similar epidemiologic behavior to paratyphoid A and B is often observed with other *Salmonella* species. A simplified typing method is urged.

BORNSTEIN, S. Epidemiologic Aspects and Laboratory Diagnoses of *Salmonella* Infections. *New York State J. Med.* 49, 23:2215 (Dec. 1), 1942.

Chips from Old Blocks—Commonly held assumptions that grossly overweight children are victims of endocrine dysfunction are not borne out by this study. Restricting diet and fluid intake and adding vitamins did as much good as the administration of glandular extracts, but no therapy was efficacious until children became old enough to want to lose the handicap of excessive fat.

BRONSTEIN, I. P., *et al.* Obesity in Children. *J. Pediat.* 21, 4:485 (Oct.), 1942.

One Truth That Shall Not Prevail

—No evidence was disclosed in this controlled study that large doses of the ordinary vitamins have any effect upon colds when given to young adults on only a reasonably adequate diet. There is no cause to believe that this truth will affect the behavior of the millions who have succumbed to the advertisements which suggest that So-and-So's vitamin pills will cure all ailments known to man and beast.

COWAN, D. W., *et al.* Vitamins for the Prevention of Colds. *J.A.M.A.* 120, 16:1268 (Dec. 19), 1942.

Deaths in a Depression Decade

—From 1930 to 1940 the expectation of life at birth rose from 59 to 63.3 years, the increase being twice as great among negroes as among whites (though the expectation for the latter is still more than 10 years greater). Except for heart disease, cancer, and diabetes, the mortality rate of each important cause of death in 1940 was below that in 1930, and the maternal mortality rate declined uninterruptedly throughout the decade.

DORN, H. F. Changes in Mortality Rates, 1930 to 1940. *Pub. Health Rep.* 57, 49:1858 (Dec. 4), 1942.

When Polio Threatens Again—

Since poliomyelitis is probably acquired via the alimentary route, the oropharyngeal mucosa is obviously the first site of contact with virus from contaminated food or drink, and utensils or fingers. Virus administered to monkeys by stomach without mouth contamination supports this concept.

FABER, H. K., and SILVERBERG, R. J. Pathway of Invasion in a *Cynomolgus* Monkey after Oral Application of Poliomyelitis Virus. *Science.* 96, 2499:473 (Nov. 20), 1942.

January Hot Weather Hints—

Dengue, typhus and related rickettsias, relapsing fever, plague, and other infections that may await the traveler to

warmer parts of this western world are briefly reviewed for the benefit of those about to divest themselves of their red flannels in favor of linen clothes and pith helmets.

FAUST, E. C. Diseases in Warm Climates. *Pub. Health Nurs.* 34, 12:663 (Dec.), 1942.

Pneumonia Types and Typing—

Of this long and important paper, the nub that the health worker will want to remember is that, despite the great effectiveness of the sulfonamide drugs, there are some cases of pneumonia (especially of the higher pneumococcus types) that are helped by the administration of the homologous serum. Pneumonia typing is by no means a dead duck.

FINLAND, M. The Present Status of the Higher Types of Antipneumococcus Serums. *J.A.M.A.* 120, 16:1294 (Dec. 19), 1942.

Not a Very Good Year—In

Canada, 1941 was a year of epidemics. Measles, scarlet fever, and mumps were all well above averages. Infant deaths were higher than the year before as were the tuberculosis death rate and those of most of the chronic diseases among the principal causes of death.

HEAGERTY, J. J. State of Health of the People of Canada in 1941. *Canad. Pub. Health J.* 33, 11:517 (Nov.), 1942.

Antidote for Cocksurenness—Are you one of those who have become hypercritical of all governmental war efforts, poisoned perhaps by the continuous barrage of carping censure from our self-appointed Jeremiahs of press and radio? Then read this review of some of the "little" problems we have had to overcome in addition to the big ones of raising and equipping an army and a navy.

HOLMES, H. N. National Survival through Science. *Science.* 96, 2498:433 (Nov. 13), 1942.

Another Prop Neatly Pulled—

On the other hand, are you one of

those ready-believers, who has assumed right along that chaulmoogra oil is a specific against leprosy and that the only considerations are early and intensive administration? After reading this paper you will no longer pontificate glibly upon the subject. It seems that the stuff is of extremely doubtful value!

McCoy, G. W. Chaulmoogra Oil in the Treatment of Leprosy. *Pub. Health Rep.* 57, 46:1727 (Nov. 13), 1942.

Testing Insanitary Glassware—Instead of swabbing the lips of drinking glasses the proposed method involves coating the glassware with a thin film of nutrient agar which encourages the organisms to grow *in situ*. The method is simple, requires no apparatus, gives direct and accurate results. Dramatically too.

Novak, M., and Lacy, A. M. A Quantitative Method for Determining the Bacterial Count of Glassware. *Am. J. Hyg.* 36, 3:316 (Nov.), 1942.

Peerings into the Virus Shadowland—Are viruses macromolecules or small organisms? In recent electron micrographs the virus particles seem to resemble bacteria. Rod shaped viruses, like many rod shaped bacteria are uniform in width but vary greatly in length. Particles of spherical viruses like most cocci have relatively uniform diameters.

Rawlins, T. E. Recent Evidence Regarding the Nature of Viruses. *Science.* 96, 2497:425 (Nov. 6), 1942.

Words That Butter Parsnips—For the responsible, ex-sanatorium patient who may become occasionally infectious, personalized health education may be the answer, and his schooling should be done while in the sanatorium. The public health nurse should be able to do the rest, if the education were adequate—which frequently it is not.

Soderstrom, K. M. Management of Patients With Occasionally Positive Sputum after Apparently Adequate Therapy (and two companion papers). *Am. Rev. Tuberc.* 46, 5:483 (Nov.), 1942.

Fallibilities—Read this classic discussion of the present-day status of our treatment of venereal diseases even though you haven't the slightest professional contact with the subject—just for the exhilarating and pleasurable experience of seeing this so human presentation of a scientific treatise. Not twice in a blue moon will you run across as sparkling and provocative—and irritating—a paper as this. Incidentally you'll get the low down on "wonder cures," prophylaxis, and kindred controversial subjects.

Stokes, J. H. The War Time Control of Venereal Disease. *J.A.M.A.* 120, 14:1093 (Dec. 5), 1942.

 Harold Sturza, 3416 "B" St., S.E., Washington, D. C., Food Inspector and Bacteriologist Health Dept.
 Howard A. Trumbull, Owens Illinois Glass Co., Toledo, Ohio, Merchandise Manager
 Richard Viola, 5548 Delmar Ave., St. Louis, Mo., Acting Supervisor, Food Inspection Service, St. Louis Health Div.

Public Health Education

George F. Bohuslav, D.D.S., Dental Division, State Health Dept., Austin, Tex., Consultant, Dental Health Education, Maternal and Child Health Division
 D. Lois Burnett, M.A., R.N., 6840 Eastern Ave., N.W., Takoma Park, D. C., Nursing Educator, General Conference of Seventh-day Adventists
 T. W. Christiansen, Madill, Okla., Sanitarian, Tri-County Health Unit
 Agnes E. Gerding, R.N., 22 East 38th St., New York, N. Y., Assisting Teacher in Health Education, Bronx Tuberculosis and Health Committee
 Dominick J. Lacovara, Ph.D., 578 Massachusetts Ave., Boston, Mass., Medical Student, Boston City Hospital
 Vera C. Mason, R.N., 308 Mills Ave., Greenville, S. C., Public Health Nurse, U. S. Public Health Service
 Idella M. Santell, R.N., 320 W. Reynolds, Pontiac, Ill., Executive Secretary and Nurse, Livingston County Tuberculosis Assn.

Public Health Nursing Section

Doris L. Achor, M.A., Lihue, Kauai, T. H., Chief Nurse, Territorial Board of Health
 Ruth Doran, M.A., R.N., 1048 Canal Bank Bldg., New Orleans, La., Regional Consultant, Children's Bureau

Epidemiology Section

Theron D. Green, M.A., 313 Rockwell Terrace, Frederick, Md., Junior Bacteriologist, State Dept. of Health
 Helen M. Jambor, M.A., 33 Hunt St., San Francisco, Calif., Chief Psychiatric Social Worker, Psychiatric Service, City-County Health Dept.
 Edward X. Mikol, M.D., M.P.H., State Dept. of Health, Albany, N. Y., Clinic Physician, Div. of Tuberculosis
 Symmes F. Oliver, M.D., 609 American Bldg., Cincinnati, Ohio
 Helen R. Postow, 1057 Hoe Ave., Bronx, N. Y., Asst. to the Statistician and Epidemiologist, Medical Branch, Headquarters Second Service Command, Governors Island, N. Y.

Unaffiliated

Hazel Merrick, D.D.S., 808 North Spring St., Los Angeles, Calif., Chief Public Health Dentist, Los Angeles County Health Dept.
 Maurice S. Reizen, Medical Detachment at Large, Morrison Field, West Palm Beach, Fla., Adjutant, Station Hospital

DECEASED MEMBERS

Donald E. Cummings, Denver, Colo., Elected Member 1935, Elected Fellow 1941, Industrial Hygiene Section
 Charles R. Hoover, Ph.D., Middletown, Conn., Elected Member 1930, Laboratory Section
 Howard B. Mettle, M.D., St. Louis, Mo., Elected Member 1936, Elected Fellow 1939, Maternal and Child Health Section
 Blanche Potter, New York, N. Y., Elected Member 1923, Unaffiliated
 Arthur H. Thomas, Philadelphia, Pa., Elected Member 1913, Unaffiliated

DR. GEORGE T. PALMER APPOINTED TO A.P.H.A. STAFF

The American Public Health Association announces the appointment of George T. Palmer, Dr.P.H., of New York, N. Y., as Associate Field Director for the Committee on Administrative Practice, succeeding Benjamin G. Horning, M.D., M.P.H., who recently resigned to become Field Director for the W. K. Kellogg Foundation, Battle Creek, Mich.

Dr. Palmer has been Deputy Commissioner of the New York City Department of Health for the past nine years. He is a graduate of the University of Rochester in 1907 and the Massachusetts Institute of Technology in 1909 and he received his Dr.P.H. degree from the University of Michigan in 1920.

Beginning his public health service with the New Jersey State Department of Health, he was a Sanitary Inspector

until 1913, when he became chief of the investigative staff of the New York State Commission on Ventilation, engaged in experimental research in the ventilation of school buildings in New York City, in which he served until 1917. Dr. Palmer was commissioned Captain in the Sanitary Corps in the Army from 1917 to 1919, acting as assistant to Colonel Victor C. Vaughan.

He next became Epidemiologist and Deputy Commissioner in the Detroit Department of Health from 1919 to 1923, then returned to New York City, and for eleven years was Director of Research of the American Child Health Association. While in this position he directed a survey of health activities in the smaller cities of the country. This work was published under the title "A Health Survey of 86 Cities." Other work under his guidance during this period included the school health studies published in monograph form from 1929 to 1933 and the research study published in 1934 under the title "Physical Defects—The Pathway to Correction."

Dr. Palmer has been a member of the American Public Health Association

since 1911 and has participated actively in its work. He is a Charter Fellow. He has served as Chairman of the Child Health Section and is now a member of the Governing Council. He has been a member of the Committee on Administrative Practice since shortly after its formation in 1920, was Chairman of the Sub-Committee on the Appraisal Form for City Health Work and guided this form through several revisions. At present he is Chairman of the Sub-Committee on the Manual and Appraisal of Local Health Work.

He is the author of many reports and articles on public health published in the *American Journal of Public Health* and elsewhere, and participated with Dr. Henry F. Vaughan and Dr. Victor C. Vaughan in the volume on "Epidemiology and Public Health."

For a number of years he has been a special lecturer on public health administration at the Massachusetts Institute of Technology, St. Johns University, and the Long Island College of Medicine in New York, N. Y. He is also Vice-President of the New York City chapter of the American Society for Public Administration.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

POSITIONS AVAILABLE

U. S. CIVIL SERVICE COMMISSION. Public Health Nursing Consultants, 5 grades. See November *American Journal of Public Health*, or write U. S. Public Health Service, Washington, D. C.

Merit System Council, Oregon State Board of Health and Crippled Children's Division, has announced merit examinations in practically all public health fields. See November *American Journal of Public Health*, or write H. J. Sears, Merit System Supervisor, P. O. Box 88, Portland, Ore.

Indiana State Personnel Division announces that applications may be filed for positions in orthopedic nursing, medical positions (5 classes), and local public health director. See November *American Journal of Public Health*, or write Indiana State Personnel Division, 141 South Meridian Street, Indianapolis, Ind.

Physician, man or woman, as director of Division of Maternal, Child and School Hygiene in southern city department of health. Woman physician with pediatric training preferred, public health experience not essential. To operate prenatal, infant and preschool clinics and promote school health program. Salary commensurate with ability and qualifications of applicant. Apply Box J, Employment Service, A.P.H.A.

Southern state department of health seeks several obstetric and pediatric consultants, requiring a minimum of a year's residency in a specialty, immunity to draft and preferably training in public health. Men and women are eligible. Salary \$300 per month plus travel. Apply Box C, Employment Service, A.P.H.A.

Public Health Engineer and director of Division of Sanitation of a city and county health unit; population 145,000 in the Midwest. Salary \$3,180 and travel allowance. Box E, Employment Service, A.P.H.A.

The Flint Civil Service Commission will consider applications for Executive Health Officer of the Flint Department of Health. Applicants must be medical graduates with a valid license to practise medicine in Michigan or eligibility for

such license; also must have practised medicine and surgery for five or more years and had considerable experience in public health work. There will be no written test, qualification being judged solely from review of experience, education and training and an oral examination. Present incumbent is on military leave of absence under circumstances which will probably extend for a period of five years. Staff consists of over fifty professional and technically trained employees. Probable salary \$5,400. Inquiries should be directed to Foster B. Roser, Director, Flint Civil Service Commission, City Hall, Flint, Mich.

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, medical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tenn., or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

Public health nurses wanted for two-county unit in Michigan. Must be graduates with minimum of 4 months' public health training or 8 months' training under supervision. Salary \$1,800 per year with travel allowance \$35 to \$41 per month. Must drive and own a car. Address Dr. Koupal, Director Alger-Schoolcraft Health Dept., Manistique, Mich.

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sanatoria. Open competitive examinations will be held and the resulting lists are expected to be in existence for 2 years

or longer. Residence requirements are waived for professional positions.

INDUSTRIAL HYGIENISTS

The Research Section of the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md., needs chemists, physicists, and medical technicians, as well as laboratory assistants in these fields. There is also opportunity for persons without college education, specific training or experience who are interested in such positions. Women now form one-third of the employees in the Research Section.

Wanted: School Dental Supervisor to administer and operate dental program in City schools and clinics in City 50,000 population. Salary \$3,000 to \$3,600 with travel allowance. Those interested should address Dr. W. A. Browne, City Health Department, Alexandria, Va.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK, N. Y.

In view of the current active demand for trained and experienced persons in public health it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

M.D., Dr.P.H., interested mental and industrial hygiene, chief of mental hygiene clinic, on staff of psychiatric hospital, speaker, writer, author of books on health, diplomate in psychiatry, professor of psychiatry. Ineligible for military service because of age, healthy, vigorous, able

to work hard, now in private practice; would make sacrifice and accept decent but lower remuneration than present income if he could be employed in war industry, preferably New York, New Jersey, or Connecticut. United States citizen. Had important government job in last war. Speaks and writes several languages. A-504.

NEWS FROM THE FIELD

AWARD OF GORGAS MEDALS

The Association of Military Surgeons of the United States recently awarded the first three medals in honor of Major General William Crawford Gorgas to Brigadier General Jefferson Randolph Kean, retired, who was chief surgeon of the Department of Western Cuba in 1900; to Brigadier General Frederick Fuller Russell, retired, of the Harvard School of Public Health, Boston; and to Rear Admiral Edward Rhodes Stitt, who recently retired after 42 years of service in the Naval Medical Corps, including 8 years as Surgeon General. The medals have been provided by John Wyeth and Brother, Philadelphia, and consist of silver medals and checks for \$500.

VITAMIN C PLACED UNDER ALLOCATION CONTROL

The War Production Board announced on December 15 that ascorbic acid (vitamin C) had been placed under allocation control through the issuance of *General Preference Order M-269*. Development of the use of vitamin C in food and medicinal production for the armed forces was the primary cause for the action, as production was formerly geared to meet pharmaceutical needs. Present production does not meet current estimated requirements, and although production capacity is being increased, demands for 1943 probably will be more than double the 1942 figures. Enough will be available, however, it was stated, for essential civilian use. The Quartermaster Corps of the Army is using large quantities of this vitamin in the "K" and "Jungle" rations and there is a substantial demand for Lend-Lease requirements. Sorbitol, which also has

recently been placed under allocation control, is one of the principal raw materials needed for the production of vitamin C.

ROSENBERGER MEDAL AWARDED TO MISS LENROOT

Katharine Lenroot, Chief of the Children's Bureau of the Department of Labor, Washington, on December 18 received the Rosenberger Medal at a convocation of the University of Chicago. The award was in recognition of her 30 years of service to the welfare of children in North and South America. Miss Lenroot is a graduate of the University of Wisconsin, served with the Wisconsin Industrial Commission, and has been identified with the Children's Bureau since shortly after its establishment in 1912. She has served as Chief of the Children's Bureau since 1934.

PHILADELPHIA COURSE IN INDUSTRIAL MEDICINE AND HYGIENE

The Philadelphia County Medical Society and the Commission on Industrial Health and Hygiene of the Medical Society of the State of Pennsylvania have announced a postgraduate course in industrial medicine and hygiene to be offered in Philadelphia January 5 to February 27 under the direction of the Department of Public Health and Preventive Medicine of the University of Pennsylvania and the Woman's Medical College of Pennsylvania. The courses are timed from 4 to 6 P.M. on Tuesdays, Thursdays, and Saturdays, and include, among other subjects, Physical Factors and Hazards, Surgical Aspects, Disease Hazards of Industry, Toxicology, Practical Applications of Industrial Medi-

cine, Compensation and Medico-Legal Factors, and Plant Sanitation. The Chairman of the Committee in charge is Lt. Col. A. Parker Hitchens, M.C., U.S.A., Department of Preventive Medicine and Public Health, University of Pennsylvania and Sarah I. Morris, M.D., Secretary, of the Department of Preventive Medicine, Woman's Medical College of Pennsylvania.

NEW YORK CITY'S HEALTH IN 1942

Ernest Lyman Stebbins, M.D., M.P.H., New York City Commissioner of Health, reported on January 1 that the year 1942 recorded for New York City its lowest infant death rate and new low mortality rates were established for diphtheria, typhoid fever, pneumonia, tuberculosis, and appendicitis. The general death rate for 1942 was 10.0 per 1,000, the record low of 9.9 having been set in 1941. The birth rate was 17.4, the highest since 1930, and the infant mortality rate 28.8 per 1,000 births.

On the unfavorable side of the picture he recorded an increase in syphilis cases which previously had been decreasing substantially. Reported syphilis cases were up 13 per cent in 1942. The death rate from tuberculosis, all forms, per 100,000, was 46.3, currently arresting the slight rise in this rate in 1941.

In a population of over 7½ million persons there were 7 deaths from diphtheria during the year. Dr. Stebbins points out that there are 8 health districts within the city which had had no diphtheria deaths for at least 4 years, and one had had no deaths for 7 years. These districts average 250,000 population.

STAFF CHANGES IN THE MEDICAL DIVISION O.C.D.

Howard H. Potter, recently water works engineer of the Maine Public Utilities Commission, Augusta, has been

appointed Regional Sanitary Engineer of the First Civilian Defense Region, O.C.D., with headquarters in Boston. John H. Brewster, New York, now of the Second Region, formerly served as sanitary engineer for both the first and second regions.

Dr. Mark V. Ziegler, Senior Surgeon, U. S. Public Health Service, recently Public Health Service District Director in the Third District, is now Regional Medical Officer for the Third Civilian Defense Region, with headquarters in Baltimore. Dr. Ziegler succeeded Dr. W. Ross Cameron who is now assigned to the Federal Housing Administration. Dr. Lloyd H. Gaston, formerly deputy chief of Emergency Medical Service in Michigan, is assistant Regional Medical Officer.

Dr. Ford S. Williams, recently Assistant Regional Medical Officer in the Ninth Civilian Defense Region with headquarters in San Francisco, has been transferred to the Eighth Region as Assistant Regional Medical Officer. He will be associated with Dr. Witten B. Russ in the Regional Office at Dallas, Tex.

DENTAL SALVAGE PROGRAM

R. K. White, Chief of the General Salvage Branch of the Conservation Division, WPB, announced that in collaboration with the American Dental Association, A National Dental Salvage Program has been organized and will be directed by the association among all members of the dental profession.

The program, calling for the conservation of all dental material and equipment as well as the scrapping of obsolete rubber and metal objects, has been initiated to function through local dental societies.

O.C.D. BULLETIN ON SANITATION

Maintenance of sewer service in bombed areas has been one of the major difficulties confronting municipal

authorities in cities under enemy attack. To assist American municipal officials and defense councils in planning for emergencies and for the restoration of normal service following damage resulting from enemy action, the sanitary engineering section of the Medical Division of the Office of Civilian Defense has issued its second sanitary engineering bulletin, "Municipal Sanitation under War Conditions."

Sanitation problems constituting grave dangers to public health may result from direct damage to sewers or from failure of the water supply, making water carriage facilities inoperable, the bulletin points out. To meet these problems, two measures are necessary: (1) strengthening of the municipal department responsible for sewer service in both personnel and material, and (2) coöperative planning with the local defense council and other municipal departments so that they may be integrated to function in an emergency.

The bulletin emphasizes the importance of accurate and complete information on the sewerage system, such as maps and records of all critical points at which a broken line would create a serious drainage problem and interrupt service over a considerable area. Inventories of material, personnel, and equipment that could be used in the event of necessity are of value, not only to the sewer department but also to other municipal departments, public utilities, or neighboring communities. Such inventories should even include the resources of local dealers or manufacturers of building material, explosives, pipe and equipment that could be used in reconstruction of sewers, the O.C.D. sanitary engineers advise. Another point stressed is that essential equipment, personnel, and material should be distributed throughout a city to avoid loss of equipment through a chance bomb hit and to lessen the possibility

of being blocked from movement by obstructed streets.

It is urged that municipal departments work closely with defense councils in order that emergency functions may be carried out with a minimum of difficulty. For example, it is pointed out that in order to function, persons and vehicles must be identified by the proper Civilian Defense insignia. Telephone service must be integrated with that of the Control Center or it may not be available in an emergency.

Suggestions are given in the bulletin on repair of damage to sewers, including advice on inspection, emergency equipment, and special measures to provide for the flow of sewage during repair.

Three methods of emergency sanitation, to be used when interruption of water service makes water-carried waste impossible, are suggested in the bulletin: handling and disposal by individual householders, temporary disposal devices set up in territory adjacent to the affected area, and a scavenger system in which containers are collected and transported to a point of disposal.

One section of the bulletin is devoted to discussion of municipal waste collection and disposal in the event of enemy action. Little can be done to protect collection facilities against damage except to disperse collection units in several locations when not in use. New methods of disposal or changes in disposal site offer more difficulty than the maintenance of collection service. Usable material may be salvaged and combustible material may be burned near the place of origin.

The sanitary land-fill is recommended as the method of disposal that could be most readily adopted. The problem of operating an incinerator during a blackout is also discussed.

The bulletin gives brief suggestions for protection of plants, with references

to special publications of the Office of Civilian Defense on protective concealment, protective construction, and glass protection.

An appendix to the bulletin contains *Operations Letter No. 29* issued by the Office of Civilian Defense on "Utility Repair Squads" and *Operations Letter No. 37*, which explain how utility personnel may be authorized to perform their duties during blackouts; designs for emergency latrines or privies; photographs and description of a newly developed sanitary excreta bag, and a bibliography of recent literature pertinent to the subject.

SAN FRANCISCO OPENS THREE PROPHYLACTIC STATIONS

Dr. J. C. Geiger, Director of Public Health of the City and County of San Francisco, has announced the opening of three prophylactic stations to be operated by his department in coöperation with the Army and Navy. The personnel is furnished through the Army and Navy, and the supplies and equipment through the Division of Venereal Diseases of the San Francisco Health Department. The operation of the stations is said to be unique in that prophylaxis will be administered to civilians as well as to the armed forces. During the first month of operation 23 per cent of the service was to civilians.

In order to secure adequate publicity 5,000 lavatory placards were distributed through the city by members of the local health department and the armed services. Half a million leaflets advertising the locations of the stations have been distributed to armed forces in the San Francisco area.

LINDBERGH HOME TO BE V.D. TREATMENT CENTER

The New Jersey State Department of Health has announced that the former home of Charles A. Lindbergh near Hopewell will become a rapid

treatment center for venereally infected women. The estate, which includes about 400 acres in the Sourland Mountains, was given to the State of New Jersey last year by Mr. Lindbergh and his wife. It will be operated under the direction of Dr. Glenn S. Usher, the Chief of the Health Department Venereal Disease Bureau.

PSYCHIATRIC SERVICE IN VENEREAL DISEASE CLINIC

Dr. J. C. Geiger, Director of Public Health, has announced the opening of the psychiatric service of the San Francisco City Venereal Disease Clinic. The psychiatric service is established as a special field study project by the U. S. Public Health Service and offers the only psychiatric service of this type that has been established in direct conjunction with a venereal disease clinic in the United States.

The service will be based on an individualized case study plan. The purposes and objectives of the psychiatric service of the clinic are to provide a reëducation and readjustment program for girls and women who offer a promiscuous sex history and who may spread or are spreading venereal diseases. In the venereal disease epidemiologic interviews on female patients reported as sources and contacts of venereal disease public health nurses and physicians secure information as to the socio-economic background of these patients. Those cases which show maladjustment will be referred to the psychiatric service which will evaluate each case referred and will attempt through the psychiatric and case work approach to offer these patients social and economic readjustment. This psychiatric service will not attempt to assist in the readjustment of confirmed prostitutes but only the non-professional, promiscuous cases.

No residence or financial requirements prevail in so far as the psychiatric

service is concerned, and the service is in position to consider cases referred from outside sources. Arrangements will be made with various nonofficial agencies to provide funds in certain instances to carry out recommended psychiatric treatment plans. Attempts will be made to relocate the patients through coöperation of official and nonofficial agencies concerned.

The medical director of the San Francisco City Clinic is the Chief of the Division of Venereal Diseases, Dr. Richard A. Koch. The Director of the Psychiatric Service of the clinic is Dr. Ernest G. Lion, who is instructor in psychiatry at the Stanford University School of Medicine. The personnel of the service will consist of the psychiatrist, a chief psychiatric social worker, an assistant social worker, with two clerks.

ENGINEERING DEPARTMENT AT NORTH- WESTERN RECEIVES MAGNIFICENT GIFT

A bequest of more than 20 million dollars to Northwestern University in the will of Walter P. Murphy, manufacturer of railway supplies, who died on December 16, has been announced. The fund will be used to develop, maintain, and operate the Technological Institute of Northwestern University which was founded in 1939 with a gift of \$6,735,000 from the Walter P. Murphy Foundation. The Board of Trustees of the university was given freedom in deciding how the funds should be used and it is provided that instruction in science to other than engineering students is permissible. A new building, erected recently at a cost of 5 million dollars, was dedicated in 1942 and houses the departments of civil, chemical, mechanical, and electrical engineering of the institute, and the departments of physics and chemistry of the university. It is operated on the "work-study" plan in which student

engineers alternate 3 months of study on the campus with equal periods of work in coöperating industries. Approximately 95 industrial organizations in 13 states coöperate with the institute in its work-study program.

NATIONAL RESEARCH COUNCIL ORGAN- IZES COMMITTEE ON SANITARY ENGINEERING

A sanitary engineering committee has been organized at the request of the Surgeon General of the Army by the National Research Council through the Division of Medical Sciences, acting for the Committee on Medical Research of the Office of Scientific Research and Development. Through liaison officers, advice and assistance in regard to sanitary engineering problems are also furnished to the Navy and the Public Health Service.

In the formation of the committee, epidemiological and entomological advice was deemed necessary and personnel representing these sciences was included. Close liaison with the Office of the Surgeon General of the Army is maintained through the Sanitary Engineering Branch, Division of Preventive Medicine. The committee consists of Abel Wolman, Dr. Eng., Chairman; Kenneth F. Maxcy, M.D., Secretary; Harold E. Babbitt; F. C. Bishopp; V. M. Ehlers; Gordon M. Fair; H. A. Whittaker.

In the several meetings to date, the committee has devoted major efforts to the problem of procurement and training of the large number of sanitary engineering personnel required for essential war activities. In addition to the needs for sanitary engineers as commissioned officers in the Sanitary Corps of the Army, the U. S. Public Health Service and the Corps of Engineers utilize sanitary engineers on a civil service status.

The committee has also considered the sanitary engineering functions performed by the Sanitary Corps of the

Army with a view toward providing constructive suggestions on the many problems occasioned by the war, including the safeguarding of Army water supplies, the disposal of waste, and malaria control.

The program covering future activities of the committee includes a continuation of its present work on the availability of and the demand for sanitary engineering personnel; the orderly procurement of and assignment to military, semi-military, and civilian agencies of trained sanitary engineers, information on military sanitary engineering problems and their solution; and a consideration of post-war needs for sanitary engineers and the fields in which they may be most profitably utilized.

The committee has had strong liaison representation from the War Department, by the presence in the deliberations of Colonels Simmons, Hardenbergh, Prentiss, and Robinson; from the Navy by Admiral Stephenson and Commanders Cushing, Tinton and Burton; from the U. S. Public Health Service by J. K. Hoskins, and from the Selective Service in the person of Major Robert A. Bier. The National Research Council representatives in the deliberations have been Drs. Weed, Davison, Forbes, and Colonel Larkey.

LEPROSY IN THE UNITED STATES

Leprosy has been introduced into different areas of the United States with very different consequences. In Louisiana, Florida, and Texas the presence of imported cases has resulted in the establishment of foci in which the disease shows a strong tendency to perpetuate itself, while in the central northwestern states and in California the reverse prevails and the disease has shown little tendency to become established. Elsewhere in the United States leprosy transmission occurs so rarely that it is negligible from the public health point of view.

The data presented refer to experience with leprosy up to the present time. But in an age in which great changes, both social and economic, are occurring, no one can predict what unexpected influence these may have on the occurrence of leprosy as well as other diseases.

From: Observations on Epidemiology of Leprosy, by G. W. McCoy, Medical Director (R), U.S.P.H.S., *Public Health Reports*, 57, 51, 1942.

BUCHANAN MEDAL AWARDED TO SIR WILSON JAMESON

The British Royal Society, through its President, Sir Henry Dale, C.B.E., has announced that the Buchanan Medal of the Royal Society has been awarded to Sir Wilson Jameson, now Chief Medical Officer of the Ministry of Health and the Board of Education. Sir Wilson was formerly dean of the London School of Hygiene and Tropical Medicine. He is an Honorary Fellow, A.P.H.A. According to the announcement, Sir Wilson's claim to the award is based on "administrative and constructive work" of outstanding merit in the service of hygienic science. Sir Wilson "has shown himself to be a man of stimulating influence and leadership, determined and persistent in his efforts to insure that advances of medical knowledge in the laboratory, the clinic and the field shall receive prompt application in administrative practice."

DR. JOHN L. RICE APPOINTED CONSULTANT TO LEDERLE LABORATORIES

John L. Rice, M.D., who recently resigned as Commissioner of Health, New York City, has joined the staff of the Lederle Laboratories, Inc., New York, as consultant to advise on developments related to public health. Dr. Rice is immediate past President of the A.P.H.A.

A native of Connecticut and a graduate of Wesleyan University and the Johns Hopkins Medical School, Dr. Rice

has held posts with the International Health Board, Rockefeller Foundation, as district state health officer in New York, as health officer of New Haven, Conn., and as Commissioner of Health of New York City. Dr. Rice has studied municipal public health in Europe and was a member of the commission sent to the Scandinavian countries to study venereal disease control in 1936.

Lederle Laboratories was founded in 1906 by another New York City health commissioner, Dr. Ernest J. Lederle. It is a producer of sera, vaccines and related medicinal products, and of drugs used in chemotherapy.

A luncheon in honor of Dr. Rice was given at the New York Academy of Medicine on January 21 by his friends and colleagues.

PUBLIC HEALTH NURSING IN WARTIME

The extraordinary demands of the times on public health facilities together with the shortage of health personnel now creates unprecedented problems for many health officers. Since public health nurses quantitatively represent a large portion of any public health staff, the attention of health officers is called to a statement, *Maintaining Minimum Public Health Nursing in Wartime*, recently prepared by the National Organization for Public Health Nursing. A copy of this statement has been sent by the N.O.P.H.N. to every full-time health officer in the United States.

NEW GRANT FOR TEACHING AND RESEARCH IN TROPICAL MEDICINE

A 5 year program of research and teaching in tropical medicine, supported by a gift of \$150,000 from the Josiah Macy Jr. Foundation, New York, N. Y., was announced in January by Dr. Willard Cole Rappleye, dean of the College of Physicians and Surgeons of Columbia University and President of the Josiah Macy Jr. Foundation.

In announcing the gift Dr. Rappleye said that after the war it was expected that there would be an increase in the amount of tropical disease in this country because members of the armed forces will return in large numbers from countries where tropical diseases are widespread. He predicted that malaria and dysentery will be the two principal diseases. He anticipated also that increased economic and industrial aid will be provided by the United States government to tropical areas after the war, which will entail medical help to the native populations and will necessitate extensive training of doctors, nurses, and public health workers.

A regular department of tropical medicine will be set up in the De Lamar Institute of Public Health at Columbia University, of which Harry S. Mustard, M.D., is the Director. The Institute is housed in the Washington Heights Health Center, 600 West 168th Street, New York, N. Y. Coöperation is assured between the School of Tropical Medicine at the University of Puerto Rico, maintained by Columbia University, which will be used as one of a number of field stations where personnel may receive additional training in the courses to be offered.

DR. HALVERSON APPOINTED CALIFORNIA STATE HEALTH OFFICER

The appointment of Wilton L. Halverson, M.D., Dr.P.H., of Los Angeles, as State Health Officer of California has been announced by Governor Warren, to take effect in January. Dr. Halverson succeeds Bertram P. Brown, M.D., who has served for several years. Dr. Halverson was appointed County Health Officer in the Los Angeles County Department of Health in 1942 and has been given a temporary leave of absence from his Los Angeles County position. Dr. Halverson is a graduate in medicine of the College of Medical Evangelists and in public health from

Yale University. He was formerly the Health Officer of Pasadena and is Professor of Public Health and Preventive Medicine in the College of Medical Evangelists in Los Angeles.

PERSONALS

Central States

KENNETH E. BENNETT, M.D., of Strasburg, Ohio, has resigned as Health Officer of Tuscarawas County, to enter the U. S. Army Air Corps. BURT A. MARQUAND, M.D., of Denison, will continue as Health Officer of Atchison until January 1, 1944.

BERT E. CALDWELL, M.D., who for 15 years has been Executive Secretary of the American Hospital Association, Chicago, Ill., has announced his resignation, effective on the appointment of a successor.

HARRY J. DEETHS, M.D., has been appointed Health Officer of Atchison, Kans.

ROBERT A. EVANS, M.D., of Columbus, Ohio, has recently been appointed Health Officer of Franklin County.

EARL E. KLEINSCHMIDT, M.D., Dr.P.H.,* since 1938 Associate Professor and Chairman of the Department of Public Health, Preventive Medicine and Bacteriology at the Loyola University School of Medicine, Chicago, Ill., has been appointed Health Commissioner of Toledo, Ohio, succeeding JOHN L. LAVAN, M.D., Dr.P.H.,* who recently resigned to become Director of Scientific Research for the National Foundation of Infantile Paralysis, New York, N. Y.

HAROLD F. MINSHULL, M.D., of New Lexington, Ohio, Coroner of Perry County, has been chosen Health Officer of the County, succeeding the late FRANK J. CROSBIE, M.D., of New Lexington.

WALTER N. MUNDELL, M.D., of Hutchinson, Kans., has been named Health Officer of Reno County.

MILTON E. PARKER,* Manager of Production for the Beatrice Creamery Company, Chicago, Ill., participated in a four weeks orientation course at the Command and General Staff School, Fort Leavenworth, Kans., "for civilians especially selected from among civic, business and professional leaders of the country" at the invitation of Lieutenant General Brehon Somervell, A.U.S. Mr. Parker has been serving for several months as special advisor, Military Planning Division, Research and Development Branch, Office of the Quartermaster General, Washington. He has recently been elected Chairman of the Chicago Section of the Institute of Food Technologists.

ERIC P. PFEIFFER, M.D., C.P.H.,† Director of the Division of Vital Statistics, Iowa State Department of Health, Des Moines, has been placed on leave in order to return to active duty in the Army.

Eastern States

OTTO A. BESSEY, Ph.D., formerly research associate in pathology and associate in biologic chemistry, Harvard Medical School, Boston, Mass., has been named Director of the Public Health Research Institute of the City of New York, Inc., for the duration of the war, replacing RALPH S. MUCKENFUSS, M.D.,* who has been called into Army service. Dr. Bessey is also Chief of the Division of Nutrition and Physiology of the Institute. Dr. Muckenfuss's position as Director of the Bureau of Laboratories of the City Department of Health is being filled by WHEELAN D. SUTLIFF, M.D.,* as Acting Director.

JOHN R. PAUL, M.D.,† Professor of Preventive Medicine at Yale University, New Haven, Conn., delivered the third Harvey Society Lecture of the current series at the New York

Academy of Medicine in December. The subject was Poliomyelitis.

BRET RATNER, M.D.,† Clinical Professor of Pediatrics, New York University College of Medicine, has been appointed Visiting Pediatrician and Director of Pediatrics to the Sea View Hospital, New York, N. Y., to succeed BELA SCHICK, M.D., who has retired with the title of Consultant Pediatrician.

Southern States

JOHN F. BUSCH, M.D.,† has been appointed Director of the American Red Cross Medical and Health Service in the Eastern Area, with headquarters in Alexandria, Va., effective February 1. Since 1937, Dr. Busch has been Assistant to the Director of Tuberculosis Control in the Georgia State Department of Public Health, Atlanta.

JOHN L. DOROUGH, M.D., of Buffalo Cove, N. C., has been elected Health Officer of Cleburne, Ala., with headquarters in Heflin.

THOMAS H. D. GRIFFITTS, M.D., D.P.H.,† who until his recent retirement was Chief Quarantine Officer of Puerto Rico and the Virgin Islands, with headquarters in San Juan, is now Health Director of the consolidated health unit in Dade County, Miami, Fla.

WILLIAM P. JACOBS, M.D.,† of Raleigh, N. C., at one time State Health Officer, has been appointed Director of School Health Coordination in the State Board of Health. The position is subsidized by the Rockefeller Foundation and is a joint project of the State Board of Health and the State Department of Public Instruction.

JAMES A. KENNEDY, PH.D.,* Professor of Public Health and Bacteriology,

University of Louisville School of Medicine, Louisville, Ky., has been accepted for a course in tropical medicine at Tulane University of Louisiana School of Medicine, New Orleans, beginning January 4. This is one of the new fellowships recently established by the Association of American Medical Colleges under a grant from the John and Mary R. Markle Foundation. On completion of the course on February 27 Dr. Kennedy will return to the University of Louisville School of Medicine.

JOHN A. LINEBERRY, M.D., of Kenansville, N. C., has been chosen Health Officer of Harnett County, to succeed WILLIAM B. HUNTER, M.D.,† of Lillington, who has been called into active service.

FRANK M. MELTON, M.D., of LaGrange, Ky., has resigned as Health Officer of Oldham County.

HOWARD D. SCHMIDT, B.D.,† Director of the Division of Sanitary Engineering of the Tennessee State Department of Public Health, Nashville, has resigned to accept a position as Principal Sanitary Engineer at the Institute of Inter-American Affairs for work in South America.

GARLAND L. WEIDNER, M.D., of Elba, Ala., Health Officer of Coffee County, is now also in charge of Geneva County.

Western States

CLYDE A. BRIDGER,* who for 4 years was statistician with the Idaho Department of Public Health in Vital Statistics, Boise, is now instructor in mathematics at the University of Utah, Salt Lake City.

Canada

A. GRANT FLEMING, M.C., M.D., D.P.H., F.R.C.P.,* Strathcona Professor of Public Health and Preventive Medicine, McGill University, Montreal; and Medical Director,

Mosquito Vectors and Inapparent Animal Reservoirs of St. Louis and Western Equine Encephalitis Viruses*

W. McD. HAMMON, M.D., DR.P.H., W. C. REEVES, AND
M. GRAY

The George Williams Hooper Foundation for Medical Research, University of California, San Francisco, Calif.

IT seems particularly fitting to discuss here in St. Louis some recent findings on the epidemiology of the encephalitis named for this city and county.

The St. Louis epidemic of 1933¹ was up to that time the largest localized encephalitis epidemic recognized to have occurred in North America. And, only one other epidemic of encephalitis has surpassed it in numbers of cases and deaths—that of the western equine type which occurred in and about North Dakota in 1941.² The St. Louis disaster remains the most important outbreak caused by the St. Louis virus.

Since the virus of western equine encephalomyelitis is responsible for an epidemic infection of man epidemio-

logically closely parallel to that produced by the St. Louis virus, the two will be discussed together. Emphasis, however, will be placed on the St. Louis type.

Now, nine years after the original St. Louis epidemic, we feel that we are able to throw some definite light on two of the remaining unsolved problems: (1) the mode of spread, (2) methods of control. These findings which we present result not from our work alone, but culminate from all the excellent work which has been done previously.

The evolution of the problem can only be reviewed very briefly in order to permit even a sketchy presentation of the new findings. Even so, the details and numerous protocols of the laboratory experiments will have to be presented in a separate paper.

In summing up the epidemiological data at the end of the 1933 epidemic it was reported that either mosquitoes were involved as vectors, or the infection was spread by contact.³ Mosquito

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

Part of a coöperative study by the Hooper Foundation and the Washington State and Yakima County Health Departments. Aided by a grant from the National Foundation for Infantile Paralysis, Inc.

transmission in the laboratory was attempted at that time but failed.³ Some were inclined therefore to believe more strongly in the contact theory. We now understand, however, from a better acquaintance with the behavior of the virus in laboratory animals, why these early attempts at insect transmission were doomed to failure.

Since the original outbreak in St. Louis other encephalitis epidemics have been recognized as predominantly due to this virus,^{4, 5} and there have been mixed St. Louis and western equine outbreaks.^{4, 6-11} It is interesting to note in connection with this that horse infections of both a clinical and an inapparent nature have been produced by inoculation of the St. Louis virus.¹²⁻¹⁴ Similar to findings reported for the equine viruses, and contrary to earlier belief, the St. Louis virus, following a dilute subcutaneous inoculation, has been found readily in the blood of chickens,¹⁵ ducks,¹⁵ doves,¹⁶ horses,¹³ mice,¹⁷ monkeys,¹⁸ guinea pigs,¹⁵ and a rabbit.¹⁵

Antibodies to the St. Louis virus have been found in the serum of normal persons and in those convalescent from encephalitis in many parts of the United States and even in Africa.^{4-11, 19-22} Antibodies have also been demonstrated in the serum of horses and of numerous other vertebrates, both domestic and wild.^{9, 10, 13, 21, 23-26}

From the epidemiological standpoint certain very significant findings have resulted from a recent series of closely correlated field and laboratory studies made in the Yakima Valley, Wash. Both St. Louis and western equine viruses were isolated repeatedly from one species of mosquito, *Culex tarsalis* Coq.^{27, 28} Antibodies to both viruses were found in as high as 50 per cent of apparently healthy domestic fowl in that area^{23, 24} and also in a high proportion of fowl in other areas.^{25, 26, 29} No antibodies, or in some instances a

very significantly lower percentage, were found either in animals from control areas or in laboratory bred fowl.^{24-26, 30, 31} These data again suggested mosquito transmission, and in addition a large inapparent vertebrate reservoir for infection.

Mitamura and associates in Japan had previously claimed mosquito transmission of St. Louis virus by *Culex pipiens* var. *pallens* Coq.³² (This same species of mosquito was found in large numbers during the St. Louis outbreak, although the particular variety was not reported.²) However, others in this country have failed to obtain transmission with *Culex pipiens* Linn.^{3, 33} Recently, using *Culex pipiens* Linn. from California (variety at present not determined) we effected transmission to doves, baby mice, and pigeons.¹⁶ Blatner and Heys, in St. Louis,³⁴ in experiments with the dog tick, *Dermacentor variabilis* (Say), likewise recently proved that arthropod transmission was possible. However, epidemiologically, there has been no particular reason to believe this tick was an important vector during any outbreak. In St. Louis, a late statistical study made by Casey and Broun pointed to mosquitoes as probable vectors.³⁵

Many of you are acquainted with the extensive successful transmission of the western and eastern equine viruses, beginning with the work of Kelser.³⁶ Reviews of these have been presented elsewhere.³⁷⁻³⁹ *Aedes* mosquitoes, the wood tick,⁴⁰ and a cone-nosed bug⁴¹ have all been shown to be potential vectors. Epidemiologically, *Aedes* have always been considered as likely vectors. The evidence is generally held to be strongly against contact transmission for the equine viruses.

In regard to possible contact transmission of either virus there are several significant observations to be considered. Several animals can be readily infected by intranasal instillation of a

suspension of either virus. Infection by feeding however is much more difficult.⁴² St. Louis virus and western equine virus have both been isolated from the nasal washings of horses inoculated by the intracerebral route.^{12, 43} Neither observation has been confirmed yet by other workers and from reported failures it seems probable that the amount of virus present, when detectable, is small. Although attempts have been limited, neither virus has been isolated from nose and throat washings, urine, or feces of man or horse during naturally acquired infections.

From the Yakima Valley studies, reviewed above, in regard to finding antibodies in animals and to isolating viruses from mosquitoes which feed on these animals⁴⁴ and from much supportive laboratory work, we felt justified in forming a hypothesis, for both viruses, of a mosquito-animal-mosquito cycle. Hypothetically, for this area, it seemed likely that mosquitoes became infected principally from animals which fulfilled the following criteria: (1) they should be abundant; (2) they should show no apparent signs of infection, because no epizootic had ever been observed, except in horses and horses were relatively few in number; (3) they should have as a result of a small peripheral inoculation a reasonably large amount of virus circulating in the blood for more than a fleeting period of time; (4) it should theoretically be a bird because in an area where epidemics occur annually the reservoir animal should be one which does not bestow a first season's protection to its offspring by maternal transmission of antibodies, as frequently occurs in mammals. This is because laboratory experience has indicated that very young animals tend to react with higher blood-virus titers than older ones, thus are better potential sources of infection for an insect vector. This advantage would be lost if the animals

were rendered immune for the first few months of life by maternal antibodies. For the Yakima area young domestic fowl best fit all the above criteria of this hypothetical reservoir.

Since all known vertebrate infections have been of short duration and laboratory mosquito infections have been occasionally lifelong, a mosquito which winters in the adult stage, such as *Culex tarsalis* in some areas, might be advanced as a hypothetical vector for the Yakima area. It is found frequently in domestic habitats, feeds readily on domestic fowl, and was found infected in nature.

The question then, was, would this mosquito become both *infected* and *infective* with each of these two viruses as a result of feeding on domestic fowl. Our crucial laboratory experiment was thus outlined. We attempted to reproduce in the laboratory this hypothetical cycle, believed to occur naturally (mosquito-fowl-mosquito). This was not the usual type of laboratory experiment using standard laboratory animals and inoculating by highly artificial routes resulting in characteristic disease patterns and death. Nor did it employ a mosquito readily adapted to a laboratory cage colony. Instead, the animals and mosquitoes suspected were brought into a carefully screened field laboratory in the epidemic area during the epidemic season and only suspected natural routes of infection were used. No deaths or signs of illness were expected in these animals.

To determine the presence of infection in our experimental fowl, since they showed no sign of disease, it was necessary to bleed at the right time following the infective mosquito bite, and test the serum for virus by intracerebral inoculation of mice. We first determined the period during which the viruses could be detected in the blood following subcutaneous inoculation, a route which was our best means of

simulating a mosquito bite. Both viruses were usually demonstrable from about 18 hours after inoculation until 60 to 72 hours. For a single test to determine the presence of virus, 48 hours turned out to be convenient and best suited to both viruses. Further evidence of infection was obtained by making tests for antibodies on the serum drawn 15 days after inoculation. These antibody responses were usually clear-cut, but never accepted as conclusive without previous virus isolation.

The selection of suitable virus strains appeared to be of great importance. Work with the eastern equine virus,⁴⁵ yellow fever virus, and others had previously indicated that any virus which originally had the ability to invade other than neural tissues tended to lose this affinity after repeated direct brain to brain passage. This, of course, is a highly artificial route of infection, one never occurring in nature. We felt that any old "brain fixed" laboratory strain might give misleading results. We therefore used almost exclusively strains of viruses recently isolated from mosquitoes and after not more than 4 passages in the brains of animals (western equine strain F199 and St. Louis strain F103). Both fresh strains of virus had been carefully identified. Using an old laboratory strain of western equine virus delayed and hampered our work with that virus, work which was limited by the shortness of the season during which mosquitoes were available.

We used incubator chicks which were kept in mosquito free quarters for 4 to 8 weeks before use. Mosquitoes were all derived from larvae brought into the laboratory.

The fowl-insect-fowl experiments reported here were performed in a temporary field laboratory in Yakima during the summer of 1942. Virus identifications and isolations from frozen serum and mosquitoes were

carried out in the San Francisco laboratory.

ST. LOUIS VIRUS EXPERIMENTS

Preliminary transmission of the St. Louis virus to chickens by *Culex tarsalis* infected by feeding on a blood-virus suspension had been accomplished in our Texas field laboratory and has been previously reported.⁴⁶

In Yakima the St. Louis virus was repeatedly transmitted by *Culex tarsalis* from chicken to chicken during the course of two experiments. (One protocol is given in Table 1.) This same species infected from a duck transmitted the virus to chickens at various intervals during another experiment. Transmission occurred after an incubation period of 8 to 16 days in the mosquito at a temperature varying between 78° and 90° F. (night and day variation). The humidity was kept relatively constant at 85 per cent. Most transmission tests were begun 10 days after the mosquitoes fed on the infected fowl and no experiment with the St. Louis virus was prolonged over 21 days. All fowls serving as a source of infection had been inoculated subcutaneously 48 hours previously with a dilute suspension of infected mouse or guinea pig brain. In previous experiments under higher incubation temperatures with mosquitoes infected on a blood-virus suspension, incubation periods were occasionally as short as 4 days.

By feeding on blood-virus suspensions we have succeeded in demonstrating transmission, as previously reported, by *Culex pipiens*¹⁶ and by *Culex coronator* Beyer.⁴⁶ More recently, in addition and not previously reported, by *Aedes lateralis* (Meigen), *Aedes taeniorhynchus* (Wiedemann), *Aedes vexans* (Meigen) and *Theobaldia incidens*. Here are potential vectors among three genera of mosquitoes and in addition, as reported by Blattner and Heys,³⁴ a tick, *Dermacentor variabilis*.

WESTERN EQUINE VIRUS EXPERIMENTS

Work with a suitable strain of western equine virus (F199) has been more limited. Repeated transmission has occurred, nevertheless, to chickens and to guinea pigs by *Culex tarsalis* fed on a blood-virus suspension. This occurred after an incubation period of 15 days till the end of the experiments at 30 days. Incubation temperatures were again between 78° and 90° F. In one experiment using a duck as the source of infection, these mosquitoes after 10 to 18 days' incubation transmitted the virus to chickens. Infection has also occurred from *C. tarsalis* fed on guinea pigs in the classical way, with transmission to chickens after 17 and 19 days.

cone-nosed bug, especially during the inter-epidemic periods.

DISCUSSION

Thus, for both the St. Louis virus and the western equine virus the cycle suspected in nature has been reproduced: Since both the fowls and the mosquitoes used are present in large numbers in the epidemic area investigated, and have been demonstrated to be naturally infected, it seems reasonable to conclude that this cycle is a normal and an important one. Man, in contrast to the enormous number of other animals suffering from inapparent infection, appears to be an accidental host.

Caution in generalization is advised

TABLE 1

Experiment No. 17

Transmission of St. Louis Encephalitis Virus by Culex tarsalis. Source of Mosquito Infection: Chick No. 70 inoculated subcutaneously 48 hours previously.

Number of Mosquitoes Feeding on Chick No. 70: 53 Holding Temperature: 78°–86° F.

<i>Days After First Feeding</i>	<i>Number Fed</i>	<i>Experimental Animal</i>	<i>Test for Virus at 48 Hours¹</i>	<i>Neutralization Test at 15 Days</i>
6	10	Chick 72	negative	weakly positive

10	14	" 84	positive	positive
12	8	" 85	positive	positive
14	13	" 88	positive	positive
16	9	" 93	positive	negative

¹ Chicken bled 48 hours after mosquitoes fed and serum tested for presence of virus as indication of transmission.

Among the mosquitoes it was previously considered possible for only *Aedes* to transmit the western equine virus. In addition to demonstrating the vector rôle of a *Culex* we have recently effected transmission of this virus by *Theobaldia incidens* (Thomson). These had been infected by feeding on a blood-virus suspension. Thus, both the genus *Culex* and the genus *Theobaldia* in addition to *Aedes* must be considered as potential vectors for this equine virus. We must also consider the possible rôle played by the tick and the

at this point. Conditions in Yakima—a hot, irrigated, agriculturalized valley region—*may not* and *probably do not* represent conditions in some other places, as some of our studies in Texas seem to indicate.³¹ There may be numerous other vectors and of animal hosts suited to their feeding habits.

It now seems very probable that *Culex pipiens* was the important vector during the great St. Louis outbreak. It, too, is a domestic mosquito, feeding frequently on birds. Dr. Lumsden tells us that the distribution of human cases

in the county and the periphery of the city fits satisfactorily with the distribution of a domestic fowl reservoir. *Culex pipiens* and *Culex quinquefasciatus* (Say) were the predominant mosquitoes during the time of the outbreak. Since we have failed repeatedly to effect transmission by *Culex quinquefasciatus* it seems less likely to have been involved.

Because it now appears that the St. Louis virus and the western equine virus (and probably the eastern equine virus) are arthropod-borne we would like to suggest an epidemiological classification for this group of encephalitides—"the arthropod-borne virus encephalitides." This would include in addition to those recognized in this country, the Japanese B encephalitis (mosquito-borne) and the Russian spring-summer encephalitis (tick-borne). This would obviate the confusion now encountered in the use of the terms "epidemic encephalitis" and "infectious encephalitis," terms which do not exclude the von Economo type, rabies, African trypanosomiasis, and others. These other terms seem to serve no useful purpose.

In regard to control, mosquito abatement is possible, as has been repeatedly demonstrated.⁴⁷ The degree of control depends on local conditions, species breeding habits, the intelligence with which a control program is planned and carried out, and on the administrative and financial action taken.

Mosquito bite protection is an individual's responsibility, and even in the presence of severe odds much can be accomplished by means of regulation of working hours, clothing, screening, and the use of insect repellents.

Vaccination for the western equine infection, now tested on a large scale in man, appears to be practical. When and where vaccination is indicated is still a problem to be faced. It is one of definite importance to military per-

sonnel in some areas. It seems probable that a vaccine for the St. Louis virus will eventually be available, but we must depend at present on mosquito control or individual mosquito protection.

SUMMARY AND CONCLUSIONS

Field and laboratory investigations furnished data which gave rise to the hypothesis that in at least one epidemic area both St. Louis and western equine encephalitis were mosquito-borne, and that the source of mosquito infection was a huge inapparent reservoir among vertebrates, particularly domestic fowl. Since both viruses had been found in naturally infected *Culex tarsalis*, this species of mosquito was tested in the laboratory for its ability to acquire infection from fowl, and in turn to transmit it. This reproduction in the laboratory of the suspected natural cycle was effected for both viruses. It appears, therefore, that both types of encephalitis are mosquito-borne and that there probably exists an inapparent animal reservoir. However, other mosquitoes representing three genera and other arthropods are capable of transmitting the infection in the laboratory. In some areas these might serve as vectors, and in this case other vertebrate hosts might be involved as reservoirs. Control apparently should be directed primarily at the arthropod vectors, with human vaccination employed under special circumstances.

Public Health Problems Concerned in the Disposal of Garbage by Feeding It to Swine*

WILLARD H. WRIGHT, PH.D., F.A.P.H.A.

Chief, Division of Zoölogy, National Institute of Health, U. S. Public Health Service, Bethesda, Md.

THE disposal of garbage has been one of the most difficult of the many sanitary problems faced by municipal administrative officials. The incineration of this material requires a considerable capital investment, reduction has not proved to be a profitable undertaking in most municipalities, and many are not in a position to employ the sanitary fill to advantage. Consequently, a large percentage of American cities have found it necessary to utilize the hog feeding method of disposal.

During the first World War, considerable pressure was brought to bear to increase the feeding of garbage to hogs as a food conservation measure. Already similar efforts are being made in connection with the present emergency. While such efforts are entirely in order and will probably be continued of necessity, it is believed that the public health feature of such a program should not be ignored. For the past several years, the writer has had occasion to study various aspects of this problem and has been called upon from time to time to supply information regarding it to sanitary engineers and other health officials. It now seems worth while to summarize for members of the public health profession and other interested individuals some of the accumulated data.

RELATION OF GARBAGE FEEDING TO HUMAN HEALTH

Unfortunately the practice of feeding uncooked garbage to swine helps to perpetuate one of the most important parasitic diseases of man in the United States. This disease, trichinosis, is more prevalent in this country than anywhere else in the world, and its occurrence is associated to a considerable extent with the above mentioned practice.

During the past five years, studies have been conducted in the National Institute of Health to determine the distribution of the trichina parasite in different population groups. In these studies, diaphragms have been obtained from persons coming to necropsy in 168 hospitals in 37 states, the District of Columbia, and Puerto Rico. To date, material from 5,379 individuals has been examined, of which 15.9 per cent has been positive for the parasite. Many of the positive cases have represented infections with relatively small numbers of larvae and it is probable that some of the individuals involved never suffered any serious effects from their infection. However, a certain percentage had infections of a degree which would probably cause illness, even though such illness might not have been recognized as trichinosis at the time of its occurrence.

On an average, about 400 clinical cases of trichinosis are reported yearly

* Presented before the Engineering Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

to the U. S. Public Health Service. However, about one-third of the states do not require the reporting of the disease and in many others it would appear that the reporting is very casual. Each year there come to the attention of the writer in various ways scores of cases which are not reported to state boards of health. There is good evidence also that many cases of the disease are not properly diagnosed. It is apparent, therefore, that the number of cases of trichinosis on record is in no way representative of the total number which probably occur.

SOURCES OF TRICHINA INFECTION

The trichina parasite, *Trichinella spiralis*, is a small roundworm living as an adult in the small intestine, and sometimes in the large intestine, and as a larva or intermediate form in the voluntary muscles of the same individual. It is found in many carnivorous and omnivorous animals. Most human cases of trichinosis are contracted through the consumption of raw or undercooked pork.

Muscle tissue containing the infective larvae of the parasite is not only infectious for man but is capable also of transmitting infection to swine. As collected, household, hotel, and restaurant garbage usually contains scraps of pork. If this pork carries the live worms, its consumption by swine will result in infection with trichinae. If the scraps happen to have come from a piece of pork which was thoroughly cooked, there is little danger of the transmission of the parasite. However, not all pork scraps recoverable from garbage have been cooked and those which have been cooked may not have had treatment sufficient to destroy the larvae. In a large eastern city, examination of nearly 600 composite 100 gram samples of pork scraps from household garbage revealed trichina infection in 1.5 per cent

of the samples. Even though one-third of the positive samples had been cooked, they contained trichinae which were still alive.

The incidence of the trichina parasite in swine is correlated closely with the type of food on which the animals are maintained and with methods of husbandry. Very extensive surveys have been carried out by the U. S. Bureau of Animal Industry to ascertain the extent of infection in swine. Results of these surveys have been reported yearly first by Hall and then by Schwartz in the annual reports of the chief of that bureau. A summation of the data in these reports indicates that there have been examined through June 30, 1941, approximately 12,000 hogs fed on raw garbage, of which 6.2 per cent were infected, approximately 22,000 so-called grain fed hogs, of which 0.8 per cent were infected, and approximately 2,800 hogs fed on cooked garbage, of which 0.4 per cent were infected. In studies in California¹ in which the hogs examined were traced back to the farm and the type of feed ascertained, infection was found in 6.4 per cent of 1,701 hogs fed on raw garbage, in 0.6 per cent of 1,109 hogs fed on grain plus kitchen scraps, and in 0.4 per cent of 2,436 hogs fed exclusively on grain. These data, and many others which are available, indicate beyond doubt that swine maintained on raw garbage are more frequently and more heavily infected with trichinae than are those given most other kinds of feed. They also indicate that the rat plays only a minor rôle in the transmission of trichinosis to swine for the reason that rats are usually just as prevalent around plants feeding cooked garbage as around those feeding raw garbage. If the rat represented the principal source of transmission of the parasite, one would expect almost as high an incidence in hogs fed on cooked as in those maintained on raw garbage.

EXTENT OF PRACTICE OF GARBAGE FEEDING

It is difficult to secure reliable information concerning the number of persons in the United States feeding garbage to hogs, the number of swine maintained on such feed, and the total tonnage of garbage which is disposed of in this manner. In a survey conducted early in 1940 by the Bureau of Agricultural Economics of the U. S. Department of Agriculture through county agricultural agents,² replies which were received from the majority of the states indicated that the number of feeders annually feeding 100 head or more totaled 2,786. A total of 1,022,000 garbage fed hogs was reported to have been marketed annually by these feeders. The report stated that, if allowance is made for missing data, the total number of garbage fed hogs in the country runs to more than 1,250,000 per year. This would seem to be a very conservative figure since it gives no consideration to hogs produced by the very large number of persons who market less than 100 garbage fed hogs per year.

Early in 1939, the writer³ conducted a survey of municipal garbage disposal methods through questionnaires forwarded to health officers in all cities of 10,000 population and over. Replies were received from 764, or 79.3 per cent, of 964 such cities. These replies indicated that a total of 296 cities disposed of municipal garbage entirely by feeding it to swine, while an additional 107 cities disposed of part of the garbage in this manner. Thus a total of 403, or 52.7 per cent, of the 764 cities replying to the questionnaire disposed of municipally collected garbage in whole or in part by feeding to swine. In only 24 of the 403 cities was the garbage cooked before its consumption by swine. While figures are not available for the country as a whole, it is reasonable to assume that the practice is equally or more extensively preva-

lent among smaller cities and towns.

Available data indicate that the trichinosis morbidity rate is correlated closely with the practice of feeding uncooked garbage to swine. For instance, the Pacific Coast States, which rank second in the number of the cities disposing of garbage by feeding it to swine, have the highest morbidity rate of any section. The New England States, with the next highest morbidity rate, lead all other geographical areas in the number of cities using the hog feeding method of disposal.

VALUE OF GARBAGE AS A HOG FEED

The food value of garbage varies considerably according to the source of the material. Garbage from hotels and restaurants, as well as hospitals and other institutions, has a much greater food value than has material from private homes. The food value of garbage has decreased considerably during the past 10 to 15 years. Formerly a ton of garbage would produce approximately 50 to 60 lbs. of pork but more recently this value has been decreased to 30 to 40 lbs. For instance, the fattening value for hogs of Los Angeles city garbage has decreased from 68 lbs. per ton in 1932 to 31 lbs. per ton in 1939. The beginning of the depression period in 1930 marked a considerable fall in the food value of garbage, a decrease which was probably due to economies effected by the housewife. However, the value has continuously declined and it is probable that other factors, such as wider use of mechanical refrigeration in the home and the increased consumption of canned food, have had considerable influence. Whatever the factors may be, the continued decline in the food value of garbage has resulted in decreasing considerably the margin of profit for the hog feeder and has rendered the business of garbage feeding even more hazardous financially.

In general, garbage fed hogs are not

popular with the meat packers because garbage produces a soft, oily pork. The dressed carcass yield of garbage fed hogs is less, and cured pork and lard from such hogs are inferior in quality to that obtained from grain fed hogs. A considerable number of packers have indicated that condemnations are more frequent in the case of garbage fed hogs. These facts and that of buyer discrimination make it necessary to sell this type of pork at a reduced price. Consequently, most meat packers buy garbage fed hogs only at a discount; this discount averages between \$.50 and \$1.00 per 100 lbs.

COST OF GARBAGE IN RELATION TO RETURNS

The decreasing food value of garbage, packer discrimination, and price discounts are of direct concern to the garbage feeder. Unless he is able to secure quality garbage gratis or at a low figure, he is operating under distinct handicaps which at best allow only a slight margin of profit. Many hog feeders secure garbage gratis while others pay varying prices for both household and hotel and restaurant garbage. In a few places the city pays the hog feeder for the collection and disposal of the garbage. Practices in regard to charging for this refuse material vary considerably and depend somewhat on the quality or food value of the material. In some places a fixed price is asked while in other cities the cost is in relation to the market price of corn. For instance, in St. Louis, where the city sells a considerable quantity of municipally collected garbage to hog feeders, the price has ranged from \$.60 to \$1.20 per ton, depending on the price of corn. In Portland, Ore., the competition among garbage feeders for good quality garbage has resulted in prices as high as \$6.00 per ton. Obviously, the higher the price paid for the garbage, the fewer opportunities for profit there are for the feeder.

DISEASES ENCOUNTERED IN GARBAGE FED HOGS

Diseases other than trichinosis are transmitted through garbage, and the frequent occurrence of these diseases contributes to the financial hazards involved in the feeding of raw garbage to hogs. Among these diseases are hog cholera, swine erysipelas, foot and mouth disease, tuberculosis, vesicular stomatitis, and vesicular exanthema. Hog cholera is a particular scourge of garbage fed swine and many outbreaks are due to the transmission of the virus in scraps of pork in the garbage. In fact, Canada requires the cooking of garbage before its consumption by swine as a means of controlling this disease. Vesicular exanthema first appeared in garbage fed hogs in California in 1932; since that time it has occurred intermittently, each time in increasing scope, until it has become a formidable problem because of extensive monetary losses resulting from the high mortality in young pigs.

COOKING OF GARBAGE AS A MEANS OF DISEASE PREVENTION

The heat treatment of garbage in a manner sufficient to destroy viruses, bacteria, or worm larvae contained in parts thereof would seem to offer a solution to the control of many of the diseases transmitted by this material. Consequently, the cooking of garbage offers distinct advantages to the feeder.

The cooking of garbage before its consumption by swine would not completely solve the trichinosis problem because other factors enter into the transmission of the disease. However, because garbage fed hogs are on the average more frequently infected and more heavily infected with trichinae than are those maintained on most other kinds of food, the method would contribute to a considerable extent to the control of human trichinosis.

The frequent warning of the public to cook pork well has apparently been

unsuccessful in controlling this disease, since there is no evidence to indicate a reduction in the number of clinical cases over the period in which intermittent warnings have been given. The present situation warrants the application of control procedures other than a dependence on the individual to protect himself against the disease, since public health practices are far beyond the antiquated stage wherein personal responsibility is the sole guide to disease prevention.

As previously stated, Canada requires the cooking of garbage as a measure of protection against hog cholera. In England cooking regulations are in force as a means of preventing foot and mouth disease. There have been few outbreaks of human trichinosis in Canada and, until the past year, England has been particularly free of the disease. According to one authority, the occurrence of a relatively large number of cases in England recently has been associated with a wartime relaxation in the enforcement of the regulations. In the United States, Oregon and Kentucky have regulations pertaining to the cooking of garbage before its consumption by swine. In Oregon, the regulations are administered by the State Department of Agriculture, and in Kentucky by the State Department of Health. Legislation to this end has recently been enacted in New York State. A rather exhaustive inquiry into the situation in that state was made by the New York State Trichinosis Commission.⁴⁻⁵ Following the work of the commission, several pieces of legislation having a bearing on trichinosis control were enacted. These included a measure to regulate slaughter-houses, a provision for the processing for the destruction of trichinae of pork products customarily eaten without cooking by the consumer, and a bill requiring that any contract made or permit issued by a municipal corporation or any public or private institution for the disposal of

garbage shall require proper cooking of the material before it is used as a feed for swine.

Contacts with state officials and a personal survey of the situation in the two first mentioned states have led the writer to believe that little opposition has been encountered in the enforcement of the regulations and that for the most part garbage feeders have voluntarily complied with the requirements and are not dissatisfied with them. In interviews with feeders in these states, they have raised none of the objections commonly offered by individuals who have never tried the feeding of cooked garbage.

OBJECTIONS TO COOKING GARBAGE FOR HOGS

The objections to feeding cooked garbage generally come under five categories, viz.: lack of palatability, presence of injurious acids and alkalis, toxicity of citrus rinds, absence of free choice selection of food, and failure of the hogs to make adequate gains. While we have no way of measuring the gustatory preferences of a hog other than its acceptance or rejection of food, the fact that hogs do consume cooked garbage with apparent relish is in itself an answer to the argument that the cooked material lacks palatability. There is also no evidence that the cooking of garbage releases dangerous acids and alkalis not already in available form. Cooking may, however, distribute such substances throughout the material. Unless in strong concentration, the dilution of such substances by the customary addition of a large amount of water to garbage is such as to render them usually innocuous.

A frequently expressed objection to the cooking of garbage has dealt with the supposition that the cooking of citrus fruit rinds releases a poison dangerous to hogs. However, experi-

mental evidence⁶ indicates that, although they have very little food value, the cooking of the rinds results in no toxic effects.

More or less free choice selection of food material is offered when hogs are maintained on raw garbage. When the material is cooked, the animal is of course not privileged to separate out types of food not to its liking. This is a valid objection, although the ability of the animal to follow its predilections may not necessarily be correlated directly with the nutritive value of the food selected. In fact, it has been the experience of many feeders that the use of cooked garbage is more economical, since a greater portion of the material is consumed and there is much less waste.

Some feeders have reported in the past that hogs fail to make adequate gains on cooked garbage. Unfortunately most opinions of this sort are based on limited observation and are

not supported by evidence from carefully planned and executed experiments in which adequate controls have been employed. However, it is probably true that the prolonged heating of garbage at high temperatures does break down or destroy some of the nutritive elements in the material. Little is known concerning the changes brought about in garbage heated to various temperatures and under various conditions, and more experimental work is needed on this problem. In spite of the lack of knowledge on the subject, there may be offered as evidence the opinion of many of those who have fed cooked garbage to swine and who believe that advantages are to be derived from cooking the material. A majority of the feeders interviewed by the writer stated that hogs maintained on cooked garbage averaged 1 to 1½ lbs. gain per day, which is certainly a good rate of gain. Some of these individuals fed grain supplements in addition to

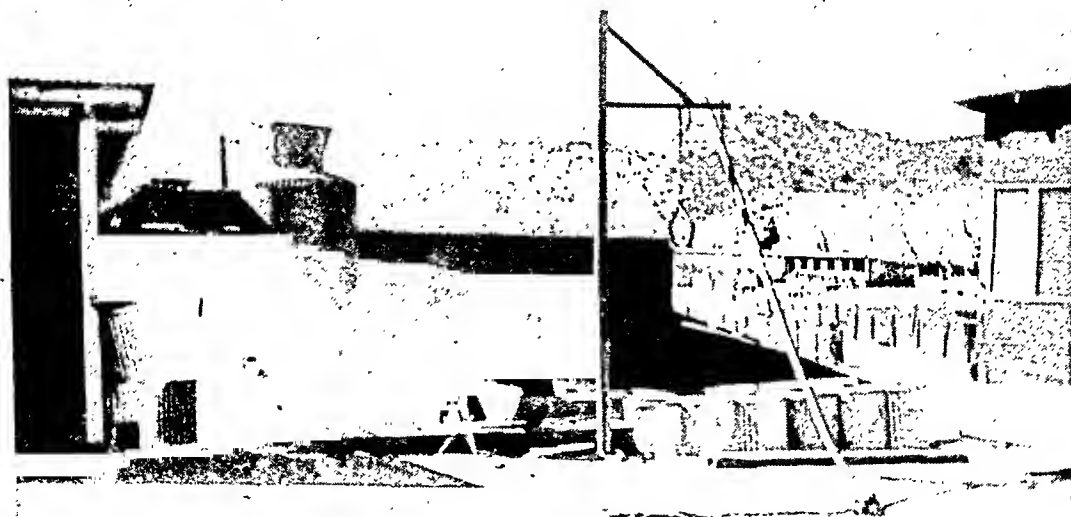

FIGURE 1—Second-hand rendering tank used for the steam cooking of garbage at the U. S. Marine Hospital, Fort Stanton, N. M.

garbage but some fed only cooked garbage.

METHODS OF PROCESSING GARBAGE

Garbage can be processed in various ways as a means of preventing disease transmission. The most practical treatment consists in boiling the material after the addition of water. This is probably the simplest and most inexpensive method of heat treatment available. In small operations, it can be accomplished by the use of equipment usually at hand or easily and inexpensively devised (Figure 1). In large scale feeding operations, equipment for boiling has not been difficult to provide and usually costs less than that needed for heat treatment by other methods. The suggested sanitation code of the U. S. Public Health Service specifies the holding of garbage to a boiling point for at least 30 minutes as a means of preventing the transmission of trichinosis. It would appear also that the transmission of many swine diseases could be obviated by this amount of heat treatment. The relative effect of the nutritive value of the material boiled for this period of time compared to that cooked for longer periods is not known. However, the experience of some hog feeders would seem to indicate that garbage boiled for long periods has less feeding value.

Various other methods have been devised for the treatment of garbage so that it may be used as a food for swine without danger of the transmission of disease. These methods involve the use of special processes which require more or less elaborate machinery and which would probably be suitable only for large scale feeding operations. However, the principles involved are interesting ones and may be capable of development to a point of practical and less expensive application.

One of these processes consists of a revolving cylinder provided between the

outer surface and the inner container with a steel jacket through which superheated air is blown by forced draft. The amount of heat applied to the garbage is controlled through escape of vapor, through the constant rotation and agitation of the material, and through the regulation of its depth over areas of varying temperature. It is possible by this process to decrease materially the moisture content of the garbage. The estimated cost of dehydrating garbage by this process varies between \$2.75 and \$3.25 per ton, depending on the scale of operation. This figure includes no allowance for labor, insurance, or interest on the money invested.

Another process which has been recommended for the dehydration of garbage and its conversion into a feed for livestock consists of a cylindrical dryer with a steam jacket surrounding the internal chamber containing the material (Figure 2). Paddles within the chamber provide a constant agitation of the material during the heating process. Chemical treatment is carried out to promote hydrolysis and steam is then applied until a pressure of 100 lbs. has been obtained. This pressure is maintained for 10 minutes, after which dehydration is accomplished by the introduction of varying amounts of vacuum in the inner chamber and a gradual lowering of the steam pressure in the outer chamber. The process is so arranged that suitable proportions of grain can be introduced through a special vacuum valve arrangement to be mixed with the garbage and provide a balanced ration. It has been estimated that the cost of treating a ton of garbage by this method amounts to approximately \$1.65. Another quite similar process, without provision for chemical treatment, has also been devised.

Of the several methods of processing garbage, experiments carried out at

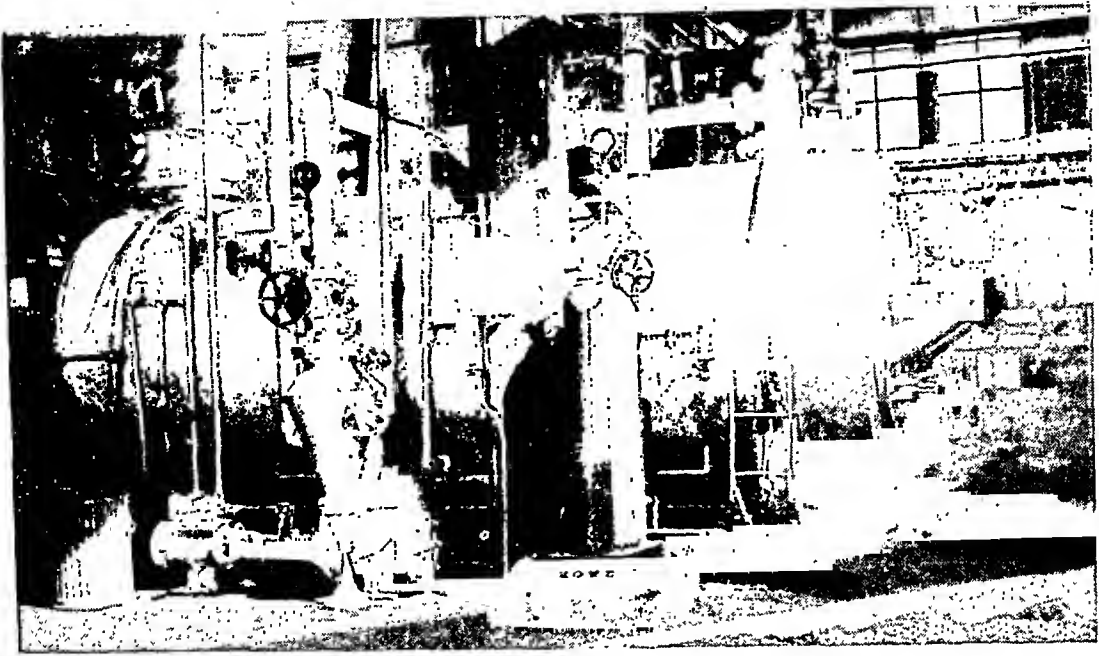

FIGURE 2—Apparatus employed for the steam-vacuum dehydration of garbage and its conversion into a feed for livestock

Courtesy American Process Feed Co., San Diego, Calif.

the California Agricultural Experiment Station under the direction of Prof. E. H. Hughes indicated that the simple heat treatment of garbage by the introduction of steam to an open container was most satisfactory from the standpoint of the food value of the product. Hogs maintained on garbage cooked in this way made better gains than did those fed the dehydrated material. Furthermore, in the feeding trials there was very little difference between the average daily gain of hogs fed on the open steam cooked garbage and raw garbage collected from the same source.

The above mentioned experiments, which are as yet unpublished, confirm the impression of the writer gathered as a result of visits to numerous garbage feeding plants and of interviews with individuals who have been feeding cooked garbage to hogs, in some cases over a long period of years. On a recent tour of such plants in a state in which there were promulgated two years ago regulations requiring the

cooking of garbage before its consumption by swine, all feeders interviewed stated that they would not return to the feeding of uncooked garbage even though the regulations were revoked. One individual who cooks and feeds 42,000 lbs. of garbage per day without the addition of any supplements advised the writer that the superiority of cooked garbage over raw garbage is so great that he considers the authorities did him a great favor in requiring him to cook the product. He stated that the cost of cooking would be more than compensated for by the extra feeding value of the cooked garbage, even though the grease salvaged from the cooked material more than covered the cost of operation. Losses had also been reduced materially since the product had been cooked. Another prominent livestock producer, who had threatened court action rather than cook garbage for hogs, later thanked the authorities for enforcing regulations and stated that he would never revert to the feeding of the raw material.

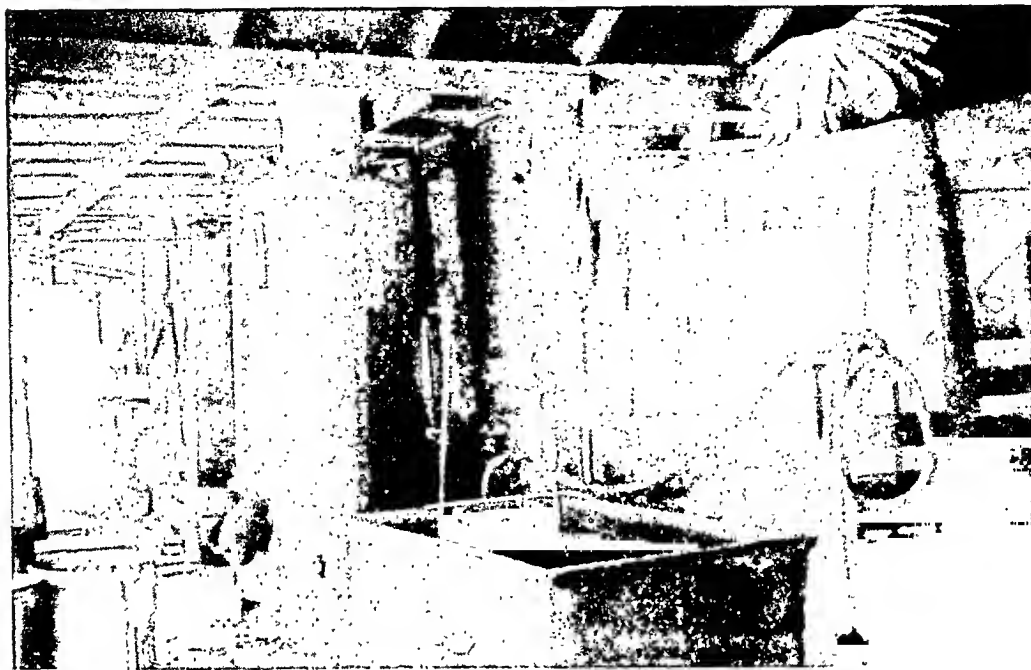

FIGURE 3—Boiler and one of the cooking tanks employed for the steam cooking of garbage for 300 hogs

COST OF EQUIPMENT FOR PROCESSING GARBAGE

The expense of installing equipment for the heat treatment of garbage varies considerably in accordance with the method of cooking, the number of hogs to be fed, the simplicity or elaborateness of the equipment, the type of fuel to be employed, and other factors. For instance, some feeders use oil burning equipment or automatic stokers which represent greater initial capital outlays but which probably pay for themselves in the long run in the saving of wages. The outlay for equipment used in the special processes mentioned above would run into thousands of dollars and would be warranted only for large scale operations. For open kettle steam cooking or direct open flame cooking, elaborate or costly equipment is not necessary and most feeders improvise equipment from discarded or second-hand materials. In order to give some practical idea as to the cost

of cooking equipment, the following is summarized from information obtained from representative feeders at the time of inspection of their operations.

F. P. On an average feeds 100 hogs; supplements garbage with grain. Collects and cooks approximately 3,750 lbs. of garbage per day. A 15 h.p. boiler and automatic stoker cost \$500 four years ago. A 500 gal. steel cooking tank cost \$20 second-hand. This is a closed tank and the garbage is cooked under steam pressure. This individual has been feeding cooked garbage for 31 years.

C. E. Maintains about 300 hogs on an average. Collects and cooks about 4,000 lbs. of garbage per day. Uses a 20 h.p. boiler (Figure 3) which cost \$400 new, and 2 steel cooking tanks which cost \$50 each new. A single steam line is run across the bottom of each tank. Each cooking tank holds 340 gal. Supplements cooked garbage with grain.

H. B. Maintains on an average about 200 hogs. Collects and cooks 4,500 lbs. of garbage per day. Pays \$1,000 per year for garbage. Uses a 10 h.p. tubular boiler which cost \$300, and an 800 gal. steel cooking tank which cost \$69.50. Steam lines are run across bottom of tank. Supplements cooked garbage with distillery waste.

B. B. Feeds on an average of 1,500 hogs. Cooked garbage is supplemented with an average of 1.5 lbs. of grain per head per day. Collects and cooks approximately 11,000 lbs. of garbage per day. The equipment consists of a 20 h.p. boiler, 2 steel cooking vats, one of 2,800 gal. and the other of 1,260 gal. capacity, and a grease vat holding 360 gal. This equipment, together with necessary feed troughs and chutes for delivering garbage cost \$1,575 installed.

B. and N. Feed an average of 2,000 hogs on cooked garbage only. Collect and cook about 21 tons of garbage per day. Equipment (Figure 4) consists of a 42 h.p. high pressure boiler, 2 steel cooking vats, one of 2,880 gal. capacity and the other of 2,231 gal. capacity, a cooling vat holding 1,260 gal., a grease vat holding 619 gal., and a storage and cooling vat holding 2,430 gal. This equipment, including necessary chutes and feeding troughs, cost \$3,278 installed.

C. J. Maintains about 12 hogs on an average. Cooks in two 50 gal. (Figure 5) oil drums, each set in a brick furnace. The oil drums and brick for the furnace were salvaged from the city dump and represent no cash outlay. Fuel consists of packing boxes and crates salvaged from the dump.

D. B. Feeds on an average of 500 hogs; supplements cooked garbage with grain approximately 2 lbs. per day per hog. Cooks and feeds 4,000 lbs. of garbage per day. Uses two 1,000 gal. steel tanks which cost \$80 each. Steam lines are run across bottom of tanks. Boiler cost \$600.

G. B. Maintains about 800 hogs on an average. Cooking equipment consists of two 2,550 gal. Douglas fir cooking vats which cost \$70 each. A marine boiler and piping cost \$500. The steam pipes are placed over the bottom and around the sides of the tanks. Supplements cooked garbage with grain at rate of 1.5 lbs. per hog per day.

Most of these observations were made and recorded prior to our active participation in the war. The situation in regard to the availability of equipment for the treatment of garbage has changed materially and it is not possible to predict whether materials will be obtainable for this purpose. No doubt the advantages of the practice from a public health standpoint will have to be weighed against the neces-

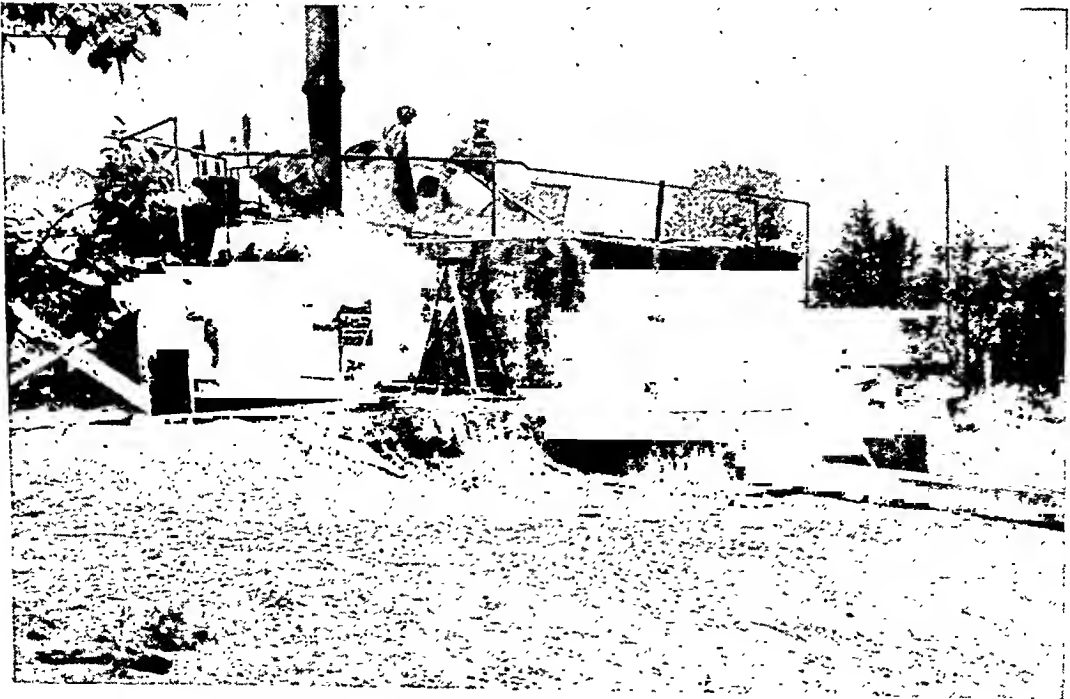

FIGURE 4—Apparatus used for the steam cooking of garbage for 2,000 hogs

sity for conserving metals for war purposes. The matter has been placed tentatively before the War Production Board and sooner or later a policy will be formulated. However, no change in the situation has taken place in other war countries, and regulations covering the cooking of garbage are still in force in Canada and England.

COST OF OPERATION

Accurate figures on the cost of cooking garbage are very difficult to obtain for the reason that most feeders do not maintain bookkeeping systems and can only estimate costs. Effort has been made by the writer to ascertain from all feeders interviewed some idea as to the cost of operating cooking equipment. The estimates furnished vary considerably, depending on the method of cooking, the section of the country, local wage scales, cost of fuel, manner of handling, and the extent to which

inedible material is removed by hand sorting either before or after cooking. Furthermore, in some of the places visited, some of the labor was furnished by the family of the feeder, in which event it was not taken into consideration in estimating costs.

Figures obtained by the writer indicate that the cost of cooking garbage varies from \$1.45 to \$3.50 per ton on the West Coast and from \$.40 to \$1.95 per ton in the South. These figures represent only the cost of labor and fuel and do not include such items as interest on the investment, depreciation; insurance, etc. In general, the cost decreases somewhat in proportion to the number of hogs fed. Information furnished the writer by Dr. Benjamin Schwartz of the U. S. Bureau of Animal Industry indicates that the cost of cooking in Canada with installations sufficient to cook garbage for 150 hogs is around \$.90 per ton.

FIGURE 5—Two 50 gallon oil drums converted for cooking of garbage over an open flame

SANITATION OF GARBAGE FEEDING
PLANTS

The general sanitation of garbage feeding plants has some bearing on the transmission of trichinosis as well as of endemic typhus and plague. These plants provide an abundance of food material for rats, and rats are usually prevalent around such plants unless proper construction is employed and suitable measures are taken to limit their spread. While the rat is of only minor importance in the transmission of trichinosis to swine, hogs do occasionally eat rats and may thus acquire trichinosis in this way.

At best the feeding of garbage to hogs creates something of a nuisance and sanitary conditions may become exceedingly bad unless constant effort is made to maintain the premises in good condition. It is best to have hog feeding plants situated in an area reasonably far removed from residential sections and preferably on land which has sufficient fall and enough natural drainage to prevent the accumulation of standing water and mud holes. Sandy soil is more suitable than heavy clay soil.

Feeding platforms should be constructed of concrete with sufficient fall to allow proper drainage into a gutter of a depth sufficient to hold the run-off of waste and wash water. The writer believes that such feeding platforms should be raised above the ground, but in any event each platform should have a rat guard of galvanized iron sheeting or concrete extending 18 in. into the subsoil. Edges of feeding platforms should extend upward at least 6 in. in order to avoid spilling garbage onto the surrounding ground area. Feeding and watering troughs should be likewise constructed of concrete with a surrounding width of concrete platform with gutters to prevent spilling. Bins for bones, tin cans, bottles and other objects salvaged from the garbage should

be constructed at least 2 ft. above ground and properly rat proofed. Bones removed from cooked garbage provide less of a nuisance than those in raw garbage. After the meat has been cooked from the bones, they bleach rapidly after being binned and usually cause no odor or fly problem.

Feeding platforms and troughs should be cleaned and washed down at least once a day and all inedible materials removed in order to maintain cleanliness and minimize fly breeding. Large scale operations should only be permitted to be carried on where the owner has sufficient land that feed lots can be changed frequently so that old lots can be turned over and if possible seeded to cover crops.

The garbage feeding plant is a focus for the potential spread of endemic typhus, plague, and trichinosis, and as such warrants supervision by local health departments. A few health jurisdictions have regulations governing the operation of such plants. In Los Angeles County, Calif., the County Live Stock Department maintains close supervision over garbage feeding plants. From the standpoint of promoting rat control and general sanitation, construction plans issued by this department are the best the writer has seen.

SUMMARY

It is pointed out that the widely prevailing practice of disposing of garbage by feeding it to swine provides an important avenue of infection for human trichinosis and a potential hazard for the spread of endemic typhus and plague. The cooking of garbage before its consumption by swine constitutes an important step in the control of human trichinosis. Objections on the part of hog feeders to this practice are discussed and evidence is offered to indicate that many feeders who now cook garbage find it feasible and economical to do so. Information is given on

methods of processing garbage and types of equipment now in use in various places. Data obtained from hog feeders on cost and operation of equipment is furnished for the benefit of sanitary engineers and others who may have occasion to deal with this problem.

NOTE: Information contained in this paper has been obtained from a wide variety of sources and the writer is indebted to those persons who have coöperated in furnishing it. Particularly is he grateful for the assistance accorded by the following individuals and organizations: Dr. A. T. McCormack, Kentucky State Health Commissioner; Mrs. Sarah Vance Dugan, Director, Bureau of Foods, Drugs, and Hotels, Kentucky State Department of Health; Dr. C. H. Blandford, Hardin County Health Officer, Elizabethtown, Ky.; M. M. Warren, Jefferson County Board of Health, Louisville, Ky.; R. E. Boyle, Manager, Fontana Farms, Fontana, Calif.; Professor E. H. Hughes, University of Cali-

fornia, College of Agriculture, Davis, Calif.; W. E. Upshaw and E. H. Jefferson, Oregon State Department of Agriculture, Portland, Ore.; the Institute of American Meat Packers, Chicago, Ill.; and J. M. Princell and Lawrence Oliver, American Process Feed Co., San Diego, Calif.

Age and Sex as Factors in the Development of the Typhoid Carrier State, and a Method for Estimating Carrier Prevalence*

WENDELL R. AMES, M.D., F.A.P.H.A., AND MORTON ROBINS, M.S.P.H.

*Commissioner, Cattaraugus County Health Department, Olean, N. Y.†; and
Statistician, Division of Communicable Diseases, New York State

AS a result of improvements in environmental sanitation, chronic typhoid carriers have assumed greater relative importance as sources of infection. Changes in typhoid incidence will probably bear a direct relationship to the prevalence of typhoid carriers, so it is of interest to estimate the current and future prevalence of these carriers. Age and sex are believed to be factors of importance in the pathogenesis of the carrier state and will be treated in this paper.

A. CHRONIC CARRIERS

Klinger¹ noted marked differences in the age distribution of what he defined as temporary and chronic carriers. The temporary carriers were predominantly children, the curve of carriers by age paralleling the curve of typhoid cases by age. Chronic carriers were rarely found among children; they were most frequently found among middle-aged adults. Stokes and Clarke,² Dean,³ Lentz,⁴ and Ledingham and Arkwright⁵ also pointed out the marked pre-

ponderance of adults, particularly adult females, among chronic carriers. Möller⁶ studied 64 chronic carriers among 7,125 recovered cases, noting that 45 were adult females, 16 were adult males, and only 3 were children. The rate of development of the carrier state in the childhood group was 0.1 per cent as contrasted with 13.5 per cent among adults. Hedrich⁷ analyzed the records of approximately 10,000 recovered cases of typhoid fever occurring in New York City between 1916 and 1926. One hundred and seventy-five of these persons had positive stools six months or longer after recovery. The observed rate of development of the carrier state among females was more than twice that among males. Moreover, the probability of developing the carrier state increased sharply with age, being about ten times as high at age 50 as at age 20.

On the other hand, Havens and Dehler⁸ attempted to determine whether typhoid carrier genesis varied with age or sex and decided that there were no differences. Similarly, Bigelow and Anderson,⁹ as a result of their studies in Massachusetts, concluded that sex differences disappeared when they

† Formerly Epidemiologist, New York State Department of Health.

considered only carriers who were derived from convalescent cases.

The records of the New York State Department of Health cover a little more than 10 years' experience relative to fecal release specimens from typhoid fever convalescents. Prior to 1929 release specimens were not required except from individuals regularly engaged in food handling occupations. The Sanitary Code was then amended, effective November 1, 1929, requiring that convalescent typhoid patients submit at least two successive negative specimens of feces before being released from supervision. The specimens must be passed not less than 3 weeks from the date of onset and at an interval of not less than 5 days. Cases among persons regularly engaged in food handling occupations are not released until they submit four successive negative specimens of feces, passed in the manner described. The Code defines a chronic fecal typhoid carrier as one whose feces contain typhoid bacilli, but who does not give a history of typhoid fever within the preceding year. By authority of these two regulations, then, fecal specimens are obtained from all individuals with typhoid fever until the requirements for release are met or until it is determined that the chronic carrier state exists.

Between January 1, 1930, and December 31, 1939, there were 3,750 cases and 433 deaths from typhoid fever reported in New York State, exclusive of New York City and state institutions. This represents a case fatality rate of 11.5 per cent, which indicates that reporting was quite complete. With the exception of 620 cases, all were followed for a sufficient length of time to determine their status according to the foregoing definitions. There were 25 who did not submit a sufficient number of specimens for release because they were not effectively followed up; 142 others who absconded or left New York State before submitting proper release specimens; and 453 who died in the attack of typhoid fever or within 1 year of the illness.

It is generally stated that 2 to 4 per cent of typhoid cases become chronic carriers. Among the 3,130 cases comprising this series, 90, or 2.9 per cent, became chronic carriers.

The rôle played by age in the development of the carrier state is shown in Table 1. Although almost half (48.9 per cent) of the typhoid cases were under 20 years of age, only 5.5 per cent of the carriers resulted from these particular cases. It appears that the probability of becoming a carrier is negligible (0.3 per cent) if typhoid is

contracted while one is less than 20 years of age. This probability increases with advancing age, reaching a maximum of 10.1 per cent among cases in the 50-59 age group.

From Table 2 it will be noted that females make up only 44.3 per cent of the cases, but comprise 58.9 per cent of the carriers. The rate of development of the carrier state at all ages is almost twice as high for females as for males. The most striking sex difference in the age-specific carrier rates occurs in the 40-49 age group in which 16.4 per cent of the female cases and only 3.5 per cent of the male cases resulted in the chronic carrier state.

disease. Cases were entered into the table as of the week in which their first fecal specimen was submitted for examination.

Certain assumptions were necessary because specimens were not submitted from all patients every week. When typhoid bacilli were found in two successive specimens submitted with more than 1 week interval, it was assumed that intervening specimens would also have been positive. Likewise, while realizing the possibility of intermittency of the carrier state, two negative specimens were considered to represent the state of affairs for all weeks between the two negative examinations. When a positive

B. CONVALESCENT CARRIERS

When these marked age and sex differences among chronic carriers were noted, it was considered desirable to study the relation of these two factors to the average frequency with which typhoid bacilli could be isolated from the feces of convalescent patients. Few such studies are reported in the literature.^{3, 9-12} The results of stool cultures for 374 cases reported during 1938 and 1939 were tabulated by sex, broad age groups, and by week after onset of the

was followed a few weeks later by a negative, with no intervening examination, it was assumed that the feces were positive for the first half of the interval and negative for the latter half. The reverse assumption was made when a negative was followed by a positive. No such assumptions were necessary, however, during the first 4 weeks following onset, and in this period the trend of the curve is definitely established.

As seen in Table 3, approximately 61 per cent of the specimens submitted

during the 1st week of illness showed typhoid bacilli, 69 per cent during the 2nd week, and 65 per cent during the

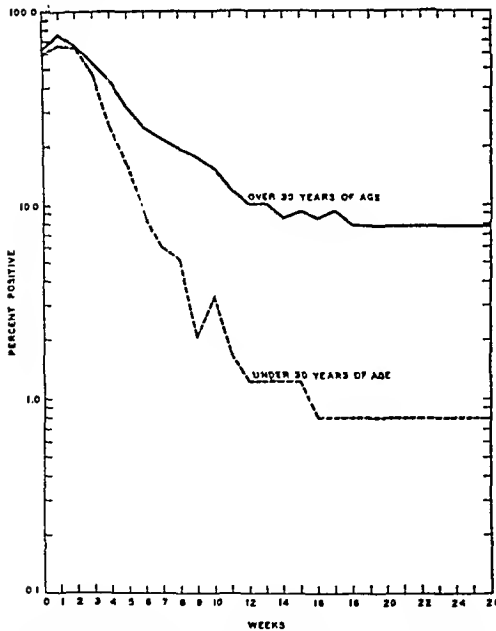

FIGURE 1—Per cent positive fecal specimens by age and week after onset of typhoid fever in New York State exclusive of New York City—374 cases 1938-1939

3rd week. From the 3rd week on there was a rapid decline until an almost constant level was reached at the 20th week.

When the data were analyzed according to sex, differences were observed but they were not statistically significant. The importance of the age factor, however, is striking (Table 3 and Figure 1). At ages 30 and over, 76 per cent of the stools were positive in the 2nd week of the disease, with a decline to 7.7 per cent in the 19th week. At ages under 30 the peak is approximately 66 per cent, also in the 2nd week, followed by a more rapid decline to 0.8 per cent in the 16th week of the disease. Fecal specimens from one female, aged 59, were found to be negative beginning in the 42nd week after the onset of illness.

C. CARRIER PREVALENCE

Estimates of carrier prevalence have recently been made in Massachusetts¹³ and Mississippi.¹⁴ In brief, the method employed in Massachusetts was as fol-

lows: The probable number of typhoid cases resulting in recovery was estimated to be equal to nine times the number of reported deaths, and 2 per cent of these survivors were assumed to be chronic carriers; the carrier prevalence in any particular year was represented by those who had become carriers during the preceding 40 years. In Mississippi, the number of persons with a history of having had typhoid fever was determined by means of a field survey of approximately 1 per cent of the population; 3.27 per cent of the persons with a history of typhoid were considered to be chronic carriers. Both methods of estimation admittedly resulted in only rough approximations. The principal deficiency in these methods is that they fail to consider the marked variations in the rates of carrier production among typhoid cases in the several age groups as shown in Table 1. A statistical technic based upon a modified life table procedure is proposed which takes into account the age distribution of carriers resulting from cases, and it may possibly give a more accurate estimate of carrier prevalence than can be ob-

tained with either of the two previously mentioned methods.

In order to apply this method, the following assumptions were made:

1. That a constant relationship has existed during the study period between the number of cases of typhoid fever and the number of deaths from the disease; a case fatality rate of 10 per cent is considered to have been maintained.

2. That the age distribution of recovered typhoid fever cases was the same during past decades as that observed during 1930-1939 (Table 1).

3. That 2.9 per cent of those patients who recover from typhoid fever remain chronic carriers; and that the rate of carrier genesis for each age group was the same in past decades as that observed during 1930-1939. As a corollary of this and the previous assumption; the age distribution of carriers produced in past decades is assumed to be the same as that observed during 1930-1939 (Table 1).

4. That carriers produced during a given decade survive to the beginning of the next decade; and that subsequent to that time they suffer the same age specific mortality risks as the general population.

5. That no carriers have been cured of their carrier condition.

It is believed that errors introduced through these assumptions do not seriously affect the final estimate of carrier

TABLE 4

Number of Typhoid Fever Deaths, Estimated Persons Surviving an Attack of Typhoid Fever and Typhoid Carriers Produced During Each Decade 1860-1939

New York State, Exclusive of New York City

<i>Decade</i>	<i>Typhoid Deaths</i>	<i>Estimated Survivors</i>	<i>Estimated Carriers Produced</i>
(1)	(2)	(col. 2 x 9)	(col. 3 x 2.9%)
(1)	(2)	(3)	(4)
1860-69	15,378 *	138,402	4,014
1870-79	13,626 *	122,634	3,556
1880-89	12,288 *	110,592	3,207
1890-99	10,953 *	98,577	2,859
1900-09	9,593	86,337	2,504
1910-19	5,236	47,124	1,367
1920-29	1,713	15,417	447
1930-39	444	3,996	116

* Typhoid deaths for each decade from 1860 to 1899 were estimated on the basis of the following mean annual typhoid death rates:

1860-1869 — 55 per 100,000 population
 1870-1879 — 45 per 100,000 population
 1880-1889 — 37 per 100,000 population
 1890-1899 — 30 per 100,000 population

prevalence in New York State. On the basis of assumptions (2) and (3), the final estimate is believed to be somewhat lowered, whereas assumptions (4) and (5) increase the final estimate.

The number of typhoid fever deaths, the estimate persons recovering from an attack of typhoid fever, and the expected number of carriers produced are shown in Table 4 for each decade since 1860. The first step in the life table procedure was to distribute the carriers according to age group at the time of their attack of typhoid (Table 5). These groups are designated as l_x cohorts.

formly distributed within the age group and assume that all 88 carriers comprising this sub-cohort survived to January 1, 1870, half of them, or 44 carriers, would still have been under 10 years of age on that date, and 44 carriers would have become 10-19 years of age (Table 6, column L_x for 1870). The latter group of 44 carriers would be over 80 years of age on January 1, 1940, and need not be considered in our further calculations. To determine how many of the 44 carriers under 10 years of age would live to enter the 10-19 age group on January 1, 1880, this number.

TABLE 5

Distribution by Age Group of the Estimated Number of Typhoid Carriers Produced During Each Decade (l_x Cohorts)

1860-1939

New York State, Exclusive of New York City

Age Group at Onset of Typhoid Fever	Per cent Total Carriers	Estimated Number Carriers Produced							
		1860- 1869	1870- 1879	1880- 1889	1890- 1899	1900- 1909	1910- 1919	1920- 1929	1930- 1939
Under 10	2.2	88	78	71	63	56	30	10	3
10-19	3.3	134	118	107	95	83	46	15	4

30-39	20.0	803	711	641	572	501	273	89	23
40-49	28.9	1,160	1,028	927	826	723	395	129	34
50-59	21.1	847	751	677	604	529	289	94	24
60-69	10.0	402	356	321	286	250	137	45	12
70-79	1.1	45	40	36	32	28	15	5	1
All ages	100.0	4,014	3,556	3,207	2,859	2,504	1,367	447	116

If we arbitrarily limit our problem to the determination of the prevalence of carriers under 80 years of age as of January 1, 1940, it becomes unnecessary to follow the life table survivorship of every carrier produced in the past. Hence, of the 4,014 carriers comprising the l_x cohort of 1860-1869, only those carriers who were under 10 years of age on January 1, 1870, are pertinent to our problem since the other carriers from this cohort would necessarily be over 80 years of age on January 1, 1940. If we assume that the carriers in this cohort under 10 years of age were uni-

multiplied by the estimated life table survivorship rate of 0.963.* Thus, it was calculated that 42 of the 44 carriers would have survived (Table 6, column C_x for 1880). The next step was to obtain the L_x cohort as of January 1, 1880. Inasmuch as carriers in this cohort who were over 20 years of age would be over 80 years of age on Janu-

* Life table survivorship rates by age group for 1910-1919, 1920-1929, and 1930-1939 were calculated from abridged life tables for New York State, exclusive of New York City. The life tables were constructed in accordance with the procedure proposed by Reed and Merrill.¹⁵ The survivorship rates obtained for 1910-1919 were used for the decades prior to 1910.

* Carriers are not included who would be over 80 years of age as of January 1, 1940.

† Values of $10p_x$ are assumed to be the same as those calculated for the decade 1910-1919.

$l_{\bar{x}}$ represents a cohort of typhoid carriers produced during a decade according to age groups x at the time of their attack of typhoid.

L_x represents a cohort of typhoid carriers according to age groups x as of January 1 of a given year.

$10p_x$ designates the probability of persons in the general population at age group x surviving to age group x + 10.

C_x represents a cohort of typhoid carriers, according to age groups x as of January 1 of a given year, who are the survivors from a preceding L_x cohort.

ary 1, 1940, only the carriers in the two sub-groups under 20 years of age are of interest. These groups were constituted as follows: the 39 carriers comprising the L_x sub-cohort under 10 years of age were derived from half the 78 carriers under 10 years of age produced between 1870 and 1879; the 140 carriers comprising the L_x sub-cohort 10-19 years of age were obtained by the addition of three groups of carriers: 39 were the other half of the 78 carriers under 10 years of age produced between 1870 and 1879; 59 were half of the 118 carriers 10-19 years of age produced between 1870-1879; and 42 were the

mentioned survivors 10-19 years of age.

The procedure described above was continued for successive decades until the L_x cohort for January 1, 1940, was obtained; the detailed computations are shown in Tables 6 and 6-A. Thus, it was estimated that 2,490 typhoid carriers under 80 years of age were living in New York State, exclusive of New York City, on January 1, 1940. The carrier prevalence rate is calculated to be 42 carriers for each 100,000 persons under 80 years of age. While no strict comparisons are justified, it is interesting to note that the carrier prevalence

* Carriers are not included who would be over 80 years of age as of January 1, 1940.

† Values of $_{10}p_x$ for the decade, 1900-1909, are assumed to be the same as those calculated for 1910-1919. For explanation of symbols, see footnote of Table 6.

rates for Massachusetts and Mississippi in 1935 were estimated to be 48 and 288 per 100,000 population, respectively.

At this point, it should be recalled that one of the basic assumptions made in calculating the New York State carrier prevalence was that 2.9 per cent of patients who recover from typhoid fever remain chronic carriers. It is realized that the true rate of carrier genesis may be higher than 2.9 per cent. The estimate may therefore be considered to be a minimum.

In Table 7 the estimated carriers are shown distributed according to age group and are related to the estimated population and to the number of carriers under supervision as of January 1,

1940. The age-specific carrier prevalence rates are observed to increase with advancing age group. The rate among children under 10 years of age was less than 1 per 100,000, whereas the rate among persons 70-79 years of age was 340 per 100,000. Of the 2,490 estimated carriers 419,* or 17 per cent, were under supervision. This percentage is shown to vary considerably with age. While only 14 per cent of the carriers over 50 years of age were known to the health authorities, the proportion of carriers under 50 years of age who were under supervision averaged 28 per cent.

Further examination of the age dis-

* Nineteen carriers under supervision are excluded who were over 80 years of age on January 1, 1940.

tribution of the estimated carriers shows that 61 per cent were between 60 and 80 years of age. In view of their advanced age, a large number of these

carriers may be expected to die annually. Using the proposed life table procedure, the future prevalence of carriers was calculated to January 1, 1980

(Table 8).^{*} Thus, it is estimated that in that year the number of carriers under 80 years of age will have decreased from 2,490 to 193.

CONCLUSIONS

1. The data presented indicate that age and sex are of importance in the development of the typhoid carrier state.

2. Typhoid patients over 30 years of age became chronic carriers nine times as frequently as did younger patients.

3. The rate of development of the carrier state at all ages was 2.1 per cent among male cases, as compared with 3.8 per cent among female cases.

4. Approximately 16 per cent of the females who developed typhoid between ages 40 and 49 became chronic carriers.

5. The rate of bacteriological cure varied inversely with age.

6. A modified life table method was applied to the typhoid experience of New York State, exclusive of New York City, and resulted in an estimated carrier prevalence on January 1, 1940, of approximately 2,500 carriers under 80 years of age, or 42 carriers per 100,000 population.

^{*} The number of carriers produced annually between 1940 and 1949 was estimated as equal to the mean number produced between 1935 and 1939. The estimated number of carriers produced in each subsequent decade was obtained by assuming that the rate of decrease between 1930-1939 and 1940-1949 continued.

7. It is highly probable that there will be a rapid decline in carrier prevalence. In 40 years it is estimated that the carrier prevalence will decrease to about 200.

8. Four hundred and nineteen, or 17 per cent, of the estimated carriers in the state were under supervision on January 1, 1940.

NOTE: The authors wish to acknowledge gratefully the advice and assistance of Dr. James E. Perkins during the preparation of the paper.

The Use of Vital Records in Military Service—The Navy*

C. S. STEPHENSON, Rear Admiral, Medical Corps, U.S.N.

AND

C. W. CHURCHILL, Lieutenant (j.g.), H-V(S), U.S.N.R.

ANY discussion of the registering of deaths, illnesses, and injuries in the Navy must be prefaced by some little discussion of the principles behind the registration process. The Medical Department of the Navy is charged with the responsibility of seeing that men recruited are physically fit. The physical standards have been long established and all recruits must meet them. After the men have entered the Navy, the Medical Department must care for them. It must see to it that they are ill as little as possible and that injuries are kept to a minimum. In other words, the Navy man must be kept fit to fight at all times. The third responsibility is that of discharging from the naval service those men who are no longer able to perform their duties.

A good system of registration of vital records must have these three responsibilities among its most important considerations. It must measure the worth of the recruiting examinations and quickly pick up those few unfit men who get by medical examiners. It must at all times show a current picture of health conditions throughout the Navy, and it must contain a mechanism which can aid most efficiently in discharging those men who are incapacitated for further duty either because of service

conditions or conditions which existed prior to their enlistment.

The vital statistics system must be simple enough to run efficiently in the midst of excitement and upset conditions incident to great naval expansion in time of war. The Navy now has men in such distant places as the Solomon Islands, the Aleutians, the South Atlantic, Iceland, and the cold waters of the North Atlantic on the route to Murmansk. Obviously a top-heavy reporting mechanism could not take care of the recording of morbidity and mortality in such out-of-the-way places of the world within any reasonable period of time. The Navy has expanded from the 150,000 men of 1939 to something over 1,300,000 today, which means that many new doctors and hospital corpsmen are responsible for the efficient basic handling of our morbidity and mortality records, and no long instruction in the handling of these records is possible.

Another fundamental requirement of the Navy's vital statistics system is that it be speedy, for nowadays an epidemic which breaks out in one ship can quickly be passed to another ship and in a short space of time to another port and even to another continent. An epidemic which breaks out in Iceland is a threat to the men of New York just as it is to men in Florida. Finally, of course, our statistics must not sacrifice all detail in order to obtain currency and simplicity.

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

To summarize briefly, our statistics must afford some measure of the effectiveness of our recruiting examinations, must give the current picture of health conditions, must indicate the need for medical discharge from the service, and must be as current and simple to administer as possible.

I shall now turn to a description of our reporting system and you may judge for yourself how well it lives up to the requirements which have been outlined. A card, called an "F" card, is made out every time a man is discharged from the sick list of any ship or station in the Navy. Because of the confining nature of naval life and the possibility of whirlwind spread of infectious diseases, admissions to the sick list and consequent isolation are rather frequent. A card is required for every discharge because a card for every admission would leave incomplete information on most cases. The time between admission and discharge from the sick list is usually so short that no great lag is created by counting all discharges rather than all admissions. If a man is admitted to the sick list aboard a destroyer because of a broken leg and then transferred to a hospital ship and finally to a hospital ashore, we will receive three cards—one for his discharge from the destroyer to the hospital ship, one from the hospital ship to the hospital ashore, and finally one from the hospital to duty when he has recovered. This example will boil down to one broken leg in our records but three "F" cards would have been received on the case.

The "F" card is a very simple form and causes comparatively little work aboard ship. It contains such fundamental data as name, race, date and place of birth, length of service, rank or rate, diagnosis, manner of admission and discharge, and the place of admission. Such items as race, date and place of birth aid us in identifying the man (or the woman, now, in the case of the

WAVES), while other items such as rank and length of service are of considerable epidemiological importance. The causative agent is an important injury item which is entered on the card.

There are four manners of admission to the sick list, and five manners of disposition. The four manners of admission are first, "new admission"; second, "readmission," for a disease or injury for which the man has already been on the sick list; third, the "EPTE," or an admission for conditions which are considered to have existed prior to entry into the Naval service; and the fourth is an "ACD," or an admission for contributory disability. An example of an "ACD" would be therapeutic poisoning as a complication of the treatment of syphilis. The five manners of disposition or discharge from the sick list are first, the disposition to "Duty"; second, "Change of Diagnosis"; third, "Death"; fourth, "Invaliding from the Service"; and the fifth is "Desertion."

You will have noticed that one of the manners of admission is an "EPTE" or admission with condition existing prior to enlistment. Such admissions measure the effectiveness of the recruiting examination, but it should be remembered that many conditions cannot be detected in a routine examination, and must await observation under service conditions before they can be discovered. Also, one of the manners of disposition is the "Invaliding from the Service," which is applied to those men who have been found to be unfit for naval service either because they were not fit to enter it or contracted some disease or injury during their service. So much for the reporting system and the "F" card.

Now let us see what uses may be made of the card after it has been received, edited, coded, and punched in the Bureau of Medicine and Surgery in Washington. In addition to the items which I have already listed, every re-

port of new admission for a venereal disease has the "probable place of exposure" noted on it. This has proved of inestimable value to venereal disease control officers, for no longer can a city claim that infected men aboard a ship based there acquired the disease elsewhere. A weekly report is now made of all venereal disease records, tabulating the probable place of exposure, and our venereal disease authorities are afforded valuable data on which to base their efforts.

As the cards are received, and even before they pass the mail desk, they can be scrutinized to see if any unusual occurrence has been reported. Daily reports can be made if necessary from cards received in the mail. This was recently found advisable in the case of jaundice which, as you all know, attracted considerable attention of late. (It was found, incidentally, that the naval service suffered little from jaundice in the past year and a half.) After the cards have been edited, coded, and given a preliminary punching for ease of filing, they are punched on another card for filing by diagnosis while the "F" cards are filed by name.

The diagnosis file becomes a fertile source of data for special studies of all sorts. Comprehensive studies have recently been made of gonorrhea, syphilis, and the more common communicable diseases such as measles, mumps, and chicken pox. The occurrence of these diseases has been investigated in connection with length of service, ship, station, occupation, age, and race. Much light has thus been shed on the problems of prevention of these diseases. For instance, it has been found that mumps, measles, chicken pox, and other diseases of this sort are more frequent in the very first weeks and months of enlistment while venereal diseases are most frequent among men in their third and fourth years of enlistment. Control measures can now be specifically aimed

at those groups where the incidence of disease is most severe.

Not long ago while the program for naval expansion was in its infancy the question arose as to whether the policy of earlier years in regard to the temporary quarantine of new recruits should be continued. In the past, recruits have been quarantined for six or eight weeks immediately after their enlistment. One of the officers of the Division of Preventive Medicine had made an excellent study of common communicable diseases and data were at hand from which to form a good judgment as to the course to follow. The data which had been prepared for previous years were quickly brought up to date and presented to the members of a conference called to consider the matter of the planning of training stations. Without the "F" cards or some very close approximations of them, it would have been necessary to have answered on the basis of "hunch" and conviction rather than facts and figures.

The present war has caused attention to be focused on the prevalence of mental diseases. One of the classes of the Diagnostic Nomenclature of the Medical Department of the Navy is called Diseases of the Mind. We have been able to bring together data for the last twenty or more years, and right up to date in this year regarding these conditions. Other studies are now under way on other conditions which I could mention at this time and they are all possible because of the ease and simplicity of the "F" card which has been in use since 1912. Many improvements have been made but the basic theories behind it have not been altered.

Though the "F" card has as one of its manners of disposition "Death," there is an additional form for deaths. It is called "Form N" and it corresponds very closely with the usual death certificates of health departments. In the past, a copy of this death certificate

has been furnished to the Bureau of the Census, insurance companies, next of kin, and other legitimately interested parties. It has been found, however, that the certificate has occasionally contained data which should not be circulated outside the naval service and a substitute form has been devised which is prepared from the death certificate in the Bureau of Medicine and Surgery and sent to the Bureau of the Census and other responsible parties. All information of a secret or confidential nature is deleted from this form.

In addition to the care of naval personnel, the Medical Department is also responsible for the industrial health of the naval establishments where many thousands of civilian employees are working in Navy Yards, Naval Air Stations, and Naval Ammunition Depots.

Every accident which occurs among these civilian employees from Panama to Alaska and Maine to California is made a matter of record. Even the minor accidents are recorded because it is felt that minor accidents are indicative of the need of preventive measures. A report is made out on every accident by the dispensary where the injured person is treated, and is sent to the Navy Department where a punch card is prepared.

Periodic studies are made of these accidents: those which are common to certain occupations, the kind of tool which is most dangerous, the previous accident record of the individual, and of the safety devices used or needed. All of this is of the utmost concern—for a day lost making a gun is as important as a day lost firing it.

The Use of Vital Records in Military Service—The Army*

LT. COLONEL GEORGE D. WILLIAMS, M.C., A.U.S.

Washington, D. C.

AS a basis for discussion, it is fitting that you first be informed concerning the kind of vital records used in the Army.

The Army keeps complete records of morbidity and mortality of its soldiers (and less complete records of other personnel), both in peace and in wartime. These records are prepared by the Army medical officers and contract surgeons of each post, camp or station. The reasons for the necessity of keeping complete records of all soldier patients were summarized by Lang¹ and Love² as follows:

1. Data are available for the conduct of the business of the War Department and other governmental agencies, with particular reference to the retention of the physically fit in the service, assignments to duty, adjustments to pay accounts and the adjudication of claims for compensation.

2. Diagnostic and therapeutic measures may be evaluated as to their effectiveness.

3. Studies of the nature of diseases may be made.

4. Data may be obtained upon which to base plans for the medical service of the Army in peace and in war. The Army's medical records constitute the most reliable and important source of its military medical experience. These records, says Love, tell the story of the early losses from diseases and non-battle injuries that occur in peace or war and the frequency and fatality of each group. They give in war a detailed account of battle casualties, tell how many occurred on each day, in what units, in what arm or

service, the anatomical location and cause of each one, the rapidity of collection and evacuation of the casualties, and the efficiency of treatment as measured by loss of time, resulting disabilities, and deaths.

5. Finally, the records are used to inform members of families concerning their soldier relative's welfare.

What personnel form the basis of the Army's medical reports?

1. Every person admitted to the station hospital, including infants born in the hospital. (Infants born on or near a military station, but not in the hospital of the station, will be reported only when the birth has been attended by a surgeon of the station.)

2. Every person, who, though not admitted to the hospital, is excused from performance of duty because of sickness or injury.

3. Every person on active duty, who, though not excused from duty, is prescribed for or treated or placed under observation with a view of treatment or with a view to discharge on account of disability.

4. Every person on active duty who is retired for disability, discharged for disability or inaptness, or dies.

5. Every person on active duty transferred to another command (i.e., sent to a general hospital from a station hospital) for observation or treatment, and every person whose case is received by transfer or evacuation from a field medical unit.

6. Every person on active duty who departs from the command on sick leave.

7. Every person in active service who is attended by a medical officer or contract surgeon in a civilian hospital.

8. Every person residing at the station or with the command, but not in the hospital, who dies.

What information is recorded for each person for whom a report is made? In peacetime and in the zone of the

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

interior (away from the battle zone) in wartime, the information obtained is: name, register number, Army serial number, grade, company, regiment or arm of service, age, race, nativity, years of service, date, source and cause of admission to report, whether or not the admission was in line of duty, change of diagnosis (if any), complications, intercurrent diseases, surgical operations, final disposition of the case with date, name of hospital, and days of treatment.

A report of sick, wounded or injured, and dead is rendered monthly to The Surgeon General from every military station and separate command which is attended by a medical officer. In time of peace and in the zone of the interior (outside the battle area) in time of war, a standard Report Card (Form 52) gives the pertinent information. This card is an exact copy of the Register Card kept by all stationary commands (including hospitals) in peacetime and by stations, general dispensaries, and fixed hospitals in the zone of the interior in wartime.

The Field Medical Record (52 c and d) and the Emergency Medical Tag (52 b) are the forms of reports used in peacetime by moving commands and by troops training in field service. In wartime in the theater of operations, the Emergency Medical Tag is the form of report used by Medical Department organizations (such as medical regiments, battalions, and squadrons) other than hospitals, where the Field Medical Record is employed. These records are attached to the clothing of the patient and travel with him until more definite disposition is made; i.e., return to duty, arrival in the zone of the interior from the theater of operations, or death.

One way in which all three of these records could be used in the case of one casualty is: a man wounded on the battlefield, when found, has attached to his clothing an Emergency Medical Tag. On arrival at an evacuation hospital,

the Emergency Medical Tag is removed and made a part of the Field Medical Record which is now created. The patient is then transferred from the evacuation hospital in the theater of operations to a general hospital in the zone of the interior. His Field Medical Record travels with him and forms the basis for making (for the first time in this case) the hospital Register Card, which is the ordinary form of report in peacetime. The Field Medical Record is now closed and forwarded directly to The Surgeon General, as is, in time, the copy of the hospital Register Card called the Report Card.

Thus the Report Card, the Field Medical Record, and the Emergency Medical Tag find their way to the Office of The Surgeon General where they form the basis of The Surgeon General's various reports, but particularly of his Annual Report. After processing (including the making of a punch card for statistical use) by the Office of The Surgeon General, the records are sent to the Office of The Adjutant General and find use as the basis of adjustment of compensation claims.

Each hospital keeps Register Cards and, in addition, the clinical record of each patient, as well as a complete outpatient record. These additional records are available to The Surgeon General for more detailed knowledge of any particular case and are of great use in cases of claims for compensation.

In addition to case reports such as those just described, current statistical reports are rendered by the surgeon of every post, camp, station, or separate command as follows:

1. A weekly statistical report relative to the number of sick, injured, and battle casualties; bed status in hospitals; first occurrence, increase, and flow of the more important communicable diseases; and the status and movement of the various stations and commands in the Army.

2. Special telegraphic reports of epidemic diseases.

3. Special reports of acute communicable diseases prevailing at stations when troops are transferred from them.

4. Reports of acute communicable diseases occurring among troops en route.

5. Reports of acute communicable diseases, births and deaths to civil health authorities.

6. Reports of births and deaths to the United States Bureau of the Census.

7. Monthly sanitary report.

8. Monthly venereal report.

It has already been stated that reports must be rendered on births in hospitals, as well as births on or near a military post if the birth is attended by a medical officer or contract surgeon. Attention also was called to the necessity of reporting on cases of communicable disease and deaths of persons in the command or of persons residing at the military station. These reports are required by the military authorities. In addition to the satisfaction of this military duty, Army regulations require that the senior Medical Officer of each station or command acquaint himself with the civil laws and regulations which govern the reporting of communicable diseases, births and deaths in the community in which the station or command is located. It is further stipulated that the original copy of such report bearing the signature of the reporting officer be forwarded to the civil office in question.

Furthermore, Army regulations require that all births and deaths occurring at military stations or in military commands in any state, territory or insular possession of the United States be reported to the Bureau of the Census. Regulations require that in submitting such reports to civil health authorities, a notation be made on the form that the case was reported to the Bureau of the Census, and vice versa.

It may happen, and does happen, that deaths in moving commands and particularly in airplane accidents may be reported to a civil authority but not in the same county or state where death

occurred. The moving of the victim of an accident to the nearest or most adequate hospital facilities may take place across an intercounty or even an interstate line. In the first instance, the coroner of the wrong county may be notified, and in the second, the report may be made to civil authorities of the wrong state. In justification, in certain instances, it may be pointed out that there exist no Chinese Great Walls between counties or states, and it is difficult at times to discover in what county or state an accidental death occurs. Aside from such peculiar and infrequent cases, there is no reason why reports of vital records referring to Army personnel should not be rendered to the proper civil authorities. The Army realizes that the report of births and deaths should form permanent records in the offices to which they are sent and that these records are often of great legal importance. This is the reason that the original copy bearing the signature of the reporting officer is the form sent to the civilian authority.

During the last war, statistics of mortality of military personnel were noted by the Bureau of the Census in tables separate from those representing the civilian population. There are advantages in this system, especially that of keeping separate tab on the armed forces and civilians. I have been informed by Dr. Dunn and Dr. Linder of the Bureau of the Census that the Army and civilians will probably be consolidated in mortality reports of this war. In any case, accurate reports on mortality will now be difficult to obtain, not so much because of incomplete reporting of deaths as because of uncertainty in estimating population bases or strengths in particular states or places. It is certain that the Army has a far more accurate estimate of its strength than the civil authorities have of their population in any place or state. This is because the Army and the armed

forces in general keep a running report of movements of personnel. The various civilian and military authorities interested in food rationing, civilian defense, social security, military security, industrial, agricultural and military manpower, and vital records have no such accurate running check on the shift or migration of population in wartime, or for that matter, at any time. It is important, if not imperative, that a system capable of being so used be devised and put into operation.

I wish to close with the remark that it is my belief and hope that the medical officers of the Army, most of them fresh from civilian life, will coöperate in this time of stress and difficulty with all local and national keepers of vital records to the utmost of their power.

Community Nursing Service During Wartime*

HORTENSE HILBERT, R.N.

*Associate Director, National Organization for Public Health Nursing,
New York, N. Y.*

THE subject of coördinated community nursing services is an old story which has, during peacetime, long been a preoccupation of progressive public health administrators and workers, and of citizens particularly interested and active in the organization and administration of public health in their communities. Now, during wartime, it takes on a new angle of urgency, if not of immediate necessity. Never has there been a more specific incentive for putting into operation in every community a plan whereby an equitable distribution can be achieved of the total supply of public health nursing that remains for the civilian population after requirements for the military population have been fully met.

The careful, conscientious social planning so important during ordinary times becomes imperative during wartime, if all wastes of man power and facilities are to be eliminated, and if the deficiencies in availability and quality of service so characteristic of a lack of social planning are to be overcome.

We are all familiar with the quantitative and qualitative disparities in public health nursing that existed in ordinary times between geographical regions, between town and country, and between individual communities. Now, in many places, movements of popula-

tion have accentuated these disparities, and in numerous communities sudden growths in population accompanied by shortages in hospital facilities and in medical and nursing personnel have brought into sharp relief the inadequacies in their health services. Health problems have been aggravated or intensified and new ones have arisen, which place greater demands than ever upon the usual public health nursing resources.

We are now faced with the dual problem of transferring public health nurses from communities where the conditions are least acute to under-served communities, and, also, of releasing eligible public health nursing personnel from civilian to military service.

When more babies are being born and fewer women can be delivered in hospitals, or when the women who are delivered in hospitals stay there for a much shorter period, then the needs for maternity nursing in the home are bound to expand. More home deliveries and discharge from hospitals early in the postpartum period mean more public health nursing, if not for direct service only, certainly for a combination of direct service and supervision and teaching of helpers of various kinds.

When there are fewer physicians at the same time that there is particular need for additional vigilance and education in the control of acute communicable disease, tuberculosis, and venereal disease, nurses with training

* Presented before the Public Health Nursing Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

and experience in the public health aspects of those conditions are also needed more than ever.

When care of children needs to be rationed because millions of women are needed in the manufacture of war materials, then the fewer real or substitute mothers who remain at home to care for children, besides or instead of their own, must be given all the help and education possible in protecting their health and welfare. Nurses with training and experience in supervising and teaching child care in the home are needed for this purpose.

When more of the chronically ill and acutely ill will be cared for at home instead of in hospitals, then more of the types of care, treatment, and instruction, usually given by physicians, will in their absence devolve upon the public health nurse.

These are but a few examples of change in the usual public health nursing situation for which every community must prepare at a time when there are fewer rather than more qualified workers.

Although most of us have no illusions about the nonproductive organizational and administrative practices that have been indulged in and are still prevalent, we realize that any confusion or disunity which hampers the fullest use of trained personnel, unconscious or unwilling as this may be, now amounts to a form of sabotage.

Some illustrations of community nursing services as organized and administered in the present year, 1942, are furnished through an N.O.P.H.N. study now in progress, of needs and organized resources for nursing care of the sick in their homes. To date 12 communities, representing as many states in the northeast, southeast, north and south central portions of the United States, have been surveyed. (Two communities in the Pacific area are to be included in the study before its com-

pletion.) One county is included in the sampling, and the 11 other areas are towns and cities ranging in size from approximately 14,000 to 120,000. Even though the communities chosen for this study were known not to have organized resources for nursing care of the sick in their homes—thus eliminating the usual public health nursing association or visiting nurse association—in some of them there still appears to be considerable decentralization of public health nursing among numerous agencies.

Only 2 of the 12 communities surveyed to date, having populations of approximately 21,000 to 25,000 respectively, have no more than 2 agencies administering public health nursing. In one of these, the county health department assumes sole responsibility for public health nursing services, and in the other the services of the county health department are supplemented by those of an insurance company. Both of these communities, which happen to be located in the deep South, are characterized by sudden large increases in population—one having doubled its population and the other having grown from approximately 25,000 to 40,000 within the last 2 years. If the ratio of public health nurses to population is any clue to adequacy of service, it is significant to note that the distribution in one of these is 1 public health nurse to 10,000, and in the other, 1 to 13,000.

Because of the proximity of these two towns to military centers, the new population outside the centers is a young one. The needs for maternal care, child health supervision, and communicable disease control and care are particularly great. At present, no home nursing care of those sick with communicable or non-communicable disease, no delivery nursing, and very limited amounts of antepartum and postpartum care are available.

Clearly, in communities such as

these, the answer is not coördination of service or of local redistribution of service, but rather one of national distribution whereby communities not having had such radical changes in population but having adequate or fairly adequate public health nursing resources would release public health nurses for civilian services in these acutely needy communities.

Among the remaining 10 communities of the 12 surveyed to date, the largest number of agencies administering public health nursing in a single community was 11—where 4 official and 7 nonofficial agencies employed 23 public health nurses for a population of about 120,000. This represents the largest city in the sampling. The ratio here is approximately 1 public health nurse to 5,000 people. Included among the 7 nonofficial agencies are 3 industrial plants, employing a total of 6 nurses for services to employees within these plants. The public health nursing services in this community are characterized by a high degree of specialization, both as to administration and types of service. For instance—

By special groups of clients: 5, or a little less than one-fourth of all public health nurses, give service only to industrial workers in the plant; 2 give service to industrial workers and their families; 1 gives service only to recipients of public assistance from the township; 3 give care only to insurance policy holders.

By age groups: 8, or more than one-third, give service only to school children.

By type of disease: 1 gives service to tuberculosis patients only; 2 give to those with venereal disease only; 1 gives to those with acute communicable disease.

This community has also witnessed a rather rapid increase in population because of the particular industries centered there. It would seem to

furnish an example of wasteful use of public health nursing personnel, besides numerical insufficiency. In this particular city, it might well be that pooling of all public health nurses and redistribution of their services on the basis of total community requirements by assigning each field nurse, regardless of administering agency, to a definite district for general service would spread the existing public health nursing personnel in a way to give a much more adequate service. As a matter of fact, although more than one-third of the public health nurses serve only the school population, nursing care of the sick, maternity nursing, and infant and preschool nursing supervision are not available except to holders of policies in insurance companies.

The fact that the shortage in hospital beds and personnel is unusually marked in this community and the ranks of physicians are being depleted rapidly, makes one wonder how this city will manage under the present circumstances.

Among the other 9 communities is one county. Here the population of about 274,000 has its public health nursing services administered by 12 agencies—9 being local boards of education, 1 a county department of health, and 2 insurance companies. The local boards of education employ 13 public health nurses, or approximately 31 per cent of all those working in the county. The health department offers a general service exclusive of care of the sick and delivery nursing, and limits its maternity nursing to patients registered for medical care in its own clinics. Two nurses engaged by an insurance company give the usual service to their policy holders.

The ratio of public health nurses to population in this county is 1 to 8,500, which would indicate that even if the direct services of all the nurses were general instead of having those of ap-

proximately one-half of them specialized either by age or special client group, care of the sick and delivery nursing in the home could not be given to any appreciable extent. Here, again, the problem seems to be more one of numerical inadequacy than one of maldistribution.

The smallest town represented in the sampling—one of slightly more than 14,000 people—has its public health nursing services divided among 7 agencies, 3 official and 4 nonofficial, as follows: a city board of health, a city board of education, one division of the state department of health, one industrial plant, two insurance companies, and one tuberculosis association. Since some of the 7 nurses give only part-time service to this community—for instance, those employed by the tuberculosis association, the state board of health, and the insurance companies—the community actually receives the equivalent of the full time of $4\frac{1}{2}$ nurses.

Here, some nursing care of the sick and maternity nursing exclusive of delivery, is given by the nurse employed by the local board of health. It is the only instance among the communities surveyed where a health department administers nursing care of the sick and also collects fees for this service.

This community would seem to be in a position to pool its varied resources to secure a better coördinated and better distributed service from the same number or a smaller number of workers. Now, when numerous agencies are involved to some extent, no preschool health supervision, no communicable disease nursing, and practically no prenatal care are available, although the ratio of public health nurses to population is 1 to about 3,000.

Of the remaining 7 cities and towns which comprise the present sampling, in 4, 3 agencies employ public health nurses, and in 3, there are 6 such

agencies. The communities in the former group range in size from approximately 98,000 to 15,000 and in the latter group from 62,000 to 10,500. Just one more example from this latter group—a town of about 15,000 population according to a 1942 estimate—where greatly increased industrial activity has resulted in population disturbances, overtaxed housing resources, and also added needs for health services.

Here, 6 separate groups are involved in the administration of public health nursing—3 separate units of the state department of health, each employing nurses separately for 3 special types of services. Two of the 3 public health nurses engaged for maternity and child health service receive some salary from the local boards of health and education. All 3 are, theoretically at least, assigned to the local board of health, whose executive officer is a layman. One state nurse is assigned for venereal disease control, and the other for epidemiological investigations of certain communicable diseases.

The nonofficial agencies employing public health nurses for services to this community are one industrial plant, one combination visiting nurse and tuberculosis association, and one insurance company. Although the actual number of public health nurses giving some service is 8, it is really the equivalent of the time of 6 full-time nurses.

Using the estimated population figure of 15,000, the ratio of nurses to population would be 1 to 2,500. This very favorable ratio would lead one to expect a comprehensive service, but the survey revealed that only policy holders in one insurance company received nursing care of the sick in the home; that there is no home delivery nursing, and no communicable disease nursing besides epidemiological investigations of certain diseases.

This community seems to afford an illustration of uneconomical use of existing resources through over-specialization, both of administration and direct service, which, in spite of its apparent quantitative adequacy, makes for definite lapses in service. Coördination of the public health nursing services of this community might well overcome these disadvantages, and gain the added advantage of releasing some of the present personnel for services in more needy and inadequately served communities.

When this N.O.P.H.N. survey, made in coöperation with the Metropolitan Life Insurance Company, the U. S. Public Health Service, the U. S. Children's Bureau, and the American Red Cross, is completed, it is hoped that besides showing how public health nursing is administered at the present time in places where no organized resources for care of the sick in their homes exist, it will be possible to suggest patterns of coördination for these and similar communities which if adopted will provide a service more comprehensive in scope and more equitably distributed in accordance with actual need, including nursing service to the sick in their homes.

Because guidance has been sought by many communities and agencies as they have become aware of the necessity for introducing immediate measures to compensate, at least in part, for the depletion of personnel, the N.O.P.H.N. has obtained information from numerous local sources in regard to what has already been done, what plans are under way, and what more needs to be done and can be done. This will form the basis of a statement on essential public health nursing services in wartime, which the N.O.P.H.N. expects to publish presently.* When summed up, this information shows fairly definite and uniform directions.

First, it is generally agreed that community analysis of public health nursing seems a logical first step—an analysis in which all agencies responsible for any part of this service will participate. Such an analysis might well be initiated by a local nursing council for war service.

Consideration then needs to be given to the type of coördinated administration best adapted to the particular community. In some instances, a merger of the voluntary agencies providing public health nursing services may be the answer, whereas in others, it may be a matter of agreements between voluntary and governmental agencies whereby personnel and facilities are interchanged. In some communities, the combining of voluntary and official agencies may be feasible. In this case, a single governing body, representative of the individual agencies and including wider representation as well, would need to be established.

Whatever plan for administrative coördination is decided upon, certain measures can be introduced immediately, for instance—

All public health nursing administrators, supervisors, and instructors, can join a common pool for redistribution of their services over the total number of public health nurses employed in the community for direct service, and the paid and voluntary auxiliary workers. An adequate supervisory and teaching staff is particularly important in wartime because of the larger proportion of auxiliary workers and of less experienced field nurses.

All field nurses employed in the community for direct service can also be pooled—each of them to be assigned for general services to families of a given district. As a first step toward economy of personnel, direct services by a variety of specialized workers should be eliminated.

Opportunities for all public health

* Published in the December, 1942, number of *Public Health Nursing*, p. 659, under the title "Maintaining Minimum Public Health Nursing in Wartime."

nurses in the community, regardless of former agency affiliation or special type of service, to prepare themselves for general service, including care of the sick and injured, can be provided through refresher courses.

Community mobilization of non-public health nursing personnel for all functions that do not absolutely require public health nursing training and experience, and which can be performed under the supervision of public health nurses, is quite generally under way. Both nursing and non-nursing, paid and volunteer personnel, are being considered in this connection. The value of these workers obviously depends greatly upon the provisions made for their in-service training and supervision.

Within each agency, too, adjustments can be made which will help to utilize more fully the public health nurses who remain. Modifications in administration which are being quite generally introduced are as follows:

GENERALIZATION OF DIRECT SERVICE BY
EVERY PUBLIC HEALTH NURSE
IN THE AGENCY

Provision for in-service education are especially important during wartime because the better prepared and more experienced staff nurses will have more responsibility for the supervision of the less experienced staff nurses and auxiliary workers. For this, they will need to be prepared on the job.

Decentralization or centralization of administration and service, depending upon the size of the community, transportation facilities, etc., is being studied by public health nursing agencies to discover which is more economical.

In some large urban communities, agencies employing a large number of nurses have concluded that setting up branch offices or sub-stations for less than 8 or 10 nurses is uneconomical because of the added cost of mainte-

nance. In more rural or smaller urban communities where fewer public health nurses are employed, but where transportation is a significant factor, there is a trend toward greater decentralization, both for administration and for service.

Naturally, the more uses to which a branch or sub-station can be put, the greater the economy. Medical clinics, nursing conferences, and group instruction, supervision and in-service training of regular and subsidiary staff, and services to individuals to reduce the number of home visits, are all activities that can be conducted in branch offices or sub-stations. Reduction in the number of times that nurses report to their offices is also an item in time saving.

The use of auxiliary personnel has been mentioned already in connection with community organization. Assignment of auxiliary workers, paid or volunteer, nurses or non-nurses, to any particular group, either according to diagnostic, economic, or other status, should be avoided. Work should be assigned only on the basis of the particular condition of the patient or the particular situation in the home.

Selection of cases for nursing service is particularly necessary when economy of public health nursing has to be practised as rigidly as it does during wartime. Selection should be considered at the time when the individual is referred for or seeks care and when continuation of care is planned. Securing the most pertinent information from the patient at the time when admission for care is under consideration and periodic review, both medical and nursing, of long-term cases such as tuberculosis contact, latent syphilis, and chronic conditions of many kinds, are, among others, significant factors in the mechanics of selectiveness.

Group instruction and service need to be substituted for individual service in

the home wherever possible. There are several types of service where instructions and demonstrations can be given to groups; for instance, tuberculosis, maternity, child care, home nursing and care of the sick, diabetes, heart disease, and rheumatic fever. Group education can well be directed to those responsible for care of children in day centers or foster homes, and to groups of industrial workers. Certain kinds of nursing treatments can also be given at centers at specified times to several persons instead of making visits to homes of individual patients.

More delegation of responsibility to the family will make it possible for public health nurses to devote themselves more and more to teaching and to supervising care given by others. In the home, members of the family, relatives, and neighbors will be prepared for performing many nursing functions under the supervision of qualified public health nurses, which have hitherto been given by professional nurses. Although this has long been considered desirable, it has not been put into practice as widely as necessity now demands. Assumption of more responsibility for health services presupposes education of the family by the public health nurse in the intelligent use of community health facilities.

Review of medical policies, standing orders, and outlines of work needs to be undertaken with the medical advisory

group at reasonably frequent intervals. In some communities, because of shortages of medical personnel, standing orders need to be enlarged and extended when it becomes necessary for public health nurses to give certain types of care, treatment, and instruction which were formerly given by physicians.

Recording and reporting, if simplified to the utmost, will save considerable time and effort of public health nursing personnel. The elimination of nonessential record items, avoidance of duplication of information, and streamlining of report and records systems, are all involved. As many activities as possible connected with the keeping and filing of records and reports should be delegated to clerical or auxiliary personnel. Uniformity of records and reports will prevent duplication, delays, and confusions.

Organizational and administration procedures such as these will suggest a great many others, which, if systematically applied, will prove effective in spreading the services of public health nurses as widely as possible. It is obvious that our peacetime standards can neither be retained nor attained during wartime, but I for one am convinced that if everything we have learned about public health nursing administration through our peacetime experience of the last 10 or 20 years is now consistently and universally applied, great economies of personnel can be achieved without too great a sacrifice in quality of service.

An Outbreak of Typhoid Fever Due to the Small Colony Variety of *Eberthella typhosa**

JANIE F. MORRIS, CATHERINE G. BARNES, AND
T. F. SELLERS, M.D., F.A.P.H.A.

Georgia Department of Public Health Laboratories, Atlanta, Ga.

IN September, 1940, an outbreak involving 13 cases of typhoid fever occurred among a family group of Negroes in a rural area of Twiggs County, Ga. Laboratory investigation revealed the causative organism to be the small colony variety of *Eberthella typhosa*. Clinically no significant peculiarities could be detected. There were two fatalities.

While epidemiological investigation failed to reveal a carrier source of this outbreak, it was later found that one of the family (Mamie G.) visited an unrelated home 8 miles distant in July. In this home were two children critically ill with fever. Both died on the 10th day after onset. A physician who was not called until just before the children died made a tentative diagnosis of "colitis." Two weeks later Mamie G. developed an illness which was not diagnosed by her physician. About 1 month later 13 others in the family became ill. It was not until then that laboratory studies were begun, and a diagnosis of typhoid fever was established and confirmed. It thus appears evident that the epidemic can be traced to the two children who died in July. Beyond this

point no definite information could be obtained.

Sporadic occurrence of typhoid fever due to a small colony variety of *E. typhosa* has been recognized in Georgia over a period of 6 years prior to this outbreak. From 11 patients the small colony variant was isolated 22 times from blood, feces, urine, and sputum.¹ No significant relationship of these cases was established.

While literature contains a few references to the isolation of the small colony variety of *E. typhosa* from blood and feces,^{1, 2, 3} only one report involved such isolations from an epidemic. In 1910, Jacobsen² reported an outbreak of typhoid in an insane asylum in Denmark. From 50 blood and feces cultures he obtained only 2 isolations, 1 from blood and 1 from feces. These were of the small colony variety. In a recurrent outbreak in the same institution 4 months later he isolated the small colony variant from 2 convalescents. It is reasonable to infer that this epidemic was entirely due to the small colony variety of *E. typhosa*.

Cultural characteristics of the small colony variety differ from those of typical strains of *E. typhosa*, (a) in the size of the colonies on extract and beef infusion agar, and (b) in their reaction on Russell's double sugar slants (acid

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

butt and acid slant with very small colonies). On extract and infusion agar the colonies average 0.2 and 0.3 mm. in diameter after 24 to 48 hours' incubation, but grow to a diameter of 1 to 2 mm. on agar containing utilizable sulfur, such as Endo's and bismuth sulfite plating media or Kligler's iron agar slants. Cultures of the small colony type, plated on plain agar, produce after several days' incubation a few large colonies which grow up among the small colonies, but which, on subculturing, do not revert to the small colony type. A few large colonies may also appear simultaneously with the small colonies on agar inoculated from broth cultures. It is difficult to maintain the small colony subcultures free of large colonies.

No evidence was found that this small colony phenomenon had any influence on normal antigenic behavior. Large colony substrains descending from small colony parents likewise seem to be antigenically similar to parental and to normal strains. By application of the bacteriophage typing method of Craigie and Yen⁴ all strains isolated in this study were found to belong to Type E.

This outbreak afforded an excellent opportunity of observing the persistence

of the small colony form in repeated stool culture examinations. Table 1 shows the number of isolations from each patient.

The significance of the small colony variant of *E. typhosa* is yet to be determined. However, the scanty growth on solid media not containing utilizable sulfur could well result in failure of recognition. Especially is this true when applied to Russell's or Krumwiede's sugar slants. On these media the colonies are very minute, and both butt and slant give an acid reaction which persists for several days or longer. By one unacquainted with these reactions such cultures are apt to be discarded. There is no reason to believe that small colony variants of *E. typhosa* are peculiar to Georgia, or any geographical section. It is advisable, therefore, that enteric bacteriologists include in their armamentaria one or more plating media containing sodium sulfite or its equivalent.

SUMMARY

A small epidemic of 13 cases of typhoid fever due to the small colony variety of *E. typhosa* is described.

The outstanding cultural characters

of the small colony variety of *E. typhosa* are reviewed.

It is suggested that to insure the detection of small colony variants of *E. typhosa*, laboratories engaged in enteric bacteriology employ plating media containing utilizable sulfur.

Nutritional Needs of American Youth^{*}

H. D. KRUSE, M.D., F.A.P.H.A.

Milbank Memorial Fund, New York, N. Y.

IN the past the diet of persons at certain ages or periods regarded as critical has been of special concern. Most energy in diet education has been focused and expended on the expectant mother, nursing mother, infant, and child. Actually, proper nutrition is important at all ages. That utterance has long been such a commonplace that its full import became much depreciated. Recent findings, however, have imparted to it such a newer and deeper meaning that nutrition of the adolescent, adult, and senescent, no less than of persons at the other ages and periods which up to now have so largely preëmpted our concern, take on a new importance. Accordingly, most of what I have to say applies to all ages. But I shall mention some matters that apply especially to youth, and make that period of particular significance.

In speaking of nutritional needs it is not my intention to review, one by one, each of the nutrients necessary for growth and prevention of deficiency diseases since they are familiar, in greater or lesser measure, to all of you. Rather, it is my purpose to comment on the nutritional condition of our people, and to suggest what needs to be and what may be done.

CHRONIC FORMS OF DEFICIENCY DISEASES

Several surveys in the various sections of our nation have shown the prevalence

of dietary deficiencies to be relatively high. Yet physicians have insisted that they rarely or never see deficiency diseases. For some time this has seemed to be an insolvable discrepancy, but it now turns out to be no contradiction whatsoever. By the notions of deficiency diseases which have prevailed, the physicians are quite correct in their assertions. But these notions, since they are exceedingly narrow, do not cover actual existing conditions. In speaking of deficiency diseases, physicians have been thinking of the severe acute form. Until recently none other was recognized. Almost all the medical literature bears only on the severe acute form. Nearly all animal experimentation has been aimed toward its production. Actually, there is relatively little of the severe acute condition in this country. There is much deficiency disease but it is in another guise.

Recently it has been demonstrated that there is widespread prevalence of deficiency diseases, not in the severe acute, but in new forms. It has been found that they are very prevalent in a chronic form. In biological behavior the chronic differs from the acute; whereas the acute is rapid, the chronic is slow in development and slow in response to treatment. Both the acute and chronic processes may be of any intensity from mild to marked. Much is of marked intensity. In brief, deficiency diseases have been demonstrated as widespread in previously unrecognized forms: mild acute, mild chronic, and severe chronic. Furthermore, the acute and chronic may

^{*} Presented before a Joint Session of the American School Health Association and the Food and Nutrition Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

be present together. Indeed, the most usual state is an acute, superimposed on a chronic condition. Each may be in a different stage and of a different intensity. Let me emphasize that this refers to each kind of deficiency disease.

Time is a factor in the evolution of both these forms; but it is particularly important in the development of the chronic process. For us, time is age. The prevalence and severity of these chronic processes increase with age. Most of the chronic changes have been regarded mistakenly as characteristic of senescence. Actually, however, they are deficiencies developing slowly over a lifetime. These chronic processes may be seen beginning in childhood. The lower the economic level the more frequently, the more severe, and earlier in life they occur. A boy of 12 in a low economic group may show changes in stages not usually seen in higher economic groups until late in life.

These facts indicate that our past efforts to stamp out malnutrition have as yet fallen short, in many instances far short, of perfection in performance. Further, they show the nature of malnutrition actually present in the population. To know and to appreciate this situation is a long step toward mapping appropriate measures to cope with it. But, beyond this, the new facts alter our outlook on the ways to improve existing nutritive conditions. It is appropriate, therefore, to examine the measures which have already been taken, and to modify and reshape them, where necessary, according to new views. We may have to prepare to take steps in a new direction. The problem is twofold: it is necessary to correct and to prevent.

CORRECTION OF DEFICIENCY STATES

In correction, the first step is examination of persons for appraisal of their nutritional status, for detecting deficiency states. It is necessary to locate in a community the areas presenting the

most prevalent and severe malnutrition, to identify the deficient persons, and to determine the nature of the deficiencies. When widespread deficiencies can be demonstrated, the health organization with limited personnel and funds can justify concentrating its resources on malnutrition. Usually, a health organization seeks to focus its activities on the worst areas where the need is greatest. Then too, if malnutrition is to be combated, the malnourished individuals must be identified and their deficiencies detected. Here again, the most severe nutritional cases, requiring the most effort, should be the first point of attack. In such a program of correction, the service that the private practitioner is in a position to render should not be underestimated. Most people consult the clinician professionally at some time during their lives.

Little has been done in examination and detection in the immediate past, except diagnosis of severe acute deficiencies in some hospitals. In schools, the height-weight measurements of children, which used to be conducted routinely, fell into disrepute and discard as an index of nutrition. Then followed a period in which no examinations for nutritional status were made. Now new methods are available for detection of deficiency diseases in their acute and chronic forms in any stage and degree as a means of evaluating nutritional status. At present the bottleneck is the training of personnel in these new methods. In the present unsettled and disrupted conditions, with shortage of medical personnel in civilian practice, and interruption to the supply of examining equipment, plans for training personnel may have to proceed much more slowly and on a smaller scale than in more peaceful times. It may have to await the war's end for full development. But at least the plans may be laid, and a start may be made on small-scale operation.

With the identification of the individuals with deficiency states and the nature of their deficiencies, specific therapy should be administered to them. Malnutrition is a medical problem requiring specific treatment. Unfortunately, in the past, two doctrines, entirely inadequate and misleading in principle, have been disseminated. It has been taught that change to an optimum diet is all that a person needs for correction of his deficiency states. It was implied that conversion to a good diet would correct effects of previous errors promptly and completely. It is true that the diet should be corrected: for one thing, to supply the necessary basal level of all dietary essentials; and for another, to form, restore, or inculcate proper dietary habits which will sustain the person in the future and prevent the recurrence of deficiency states once they are corrected. But specific therapy is needed for complete and effective treatment of deficiency states.

The second viewpoint has been that deficiency states respond dramatically and quickly to therapy, and that a few days' or few weeks' therapy is sufficient. That is true for the severe acute forms, the classical textbook conditions. With them, the results are often quite spectacular. But relatively few such forms occur. Most deficiency states are mixed, acute superimposed on chronic. In treating them, the symptoms of acute process vanish promptly under therapy; then the tissue changes characteristic of the acute form next disappear. The chronic lesions recede not in a few days or weeks, but only after a very long time—several years for advanced states. Clearly, the therapeutic regimen must conform to these facts.

In view of these facts, it is clear that chronic deficiency states which start in youth should be corrected then, before they have advanced to late stages where the necessarily long period of therapy makes it a more difficult, laborious, and

expensive problem to carry it to completion. Moreover, the earlier the states are detected and corrected, the earlier interest is aroused in keeping free of these states by proper diet.

These deficiency states, moreover, are accompanied by unpleasant and handicapping symptoms. Also, there are strong indications that these states developing insidiously predispose to more serious, overshadowing diseases. With new tools we are on the threshold of testing that hypothesis. If it is found to be true, the earlier the deficiency states are corrected, the less should be morbidity and premature mortality. It is not fanciful to presume that prompt correction of deficiency disorders, adding very considerably to the number of years in excellent nutrition, would bring a healthier, happier, and longer life.

PREVENTION OF DEFICIENCY STATES

It is necessary, not only to correct, but also to prevent deficiency states. Either step alone, would constitute an incomplete program. Because correction is so expensive, it is especially important to stress prevention. Once deficiency states in a person are corrected, it is essential to prevent recurrence. Better still, it should be the goal to prevent these states from ever occurring. That emphasizes the necessity of starting the preventive work early in life, and underscores the work with youth. Much of this preventive work takes the form of education in proper dietary habits. One of the outstanding effects of finding chronic malnutrition so prevalent is the impressive realization that diet education has an even greater importance than has previously been appreciated, that it must be extended to the utmost, and that it must be raised to new heights of effectiveness.

In view of our new insight into conditions and the greater significance to be attached to diet education, it would be wise to consider whether the program

as conducted at present will satisfactorily fulfil its purpose. Our new conception of the problem may call for a new rationale and design of action. In the past it has been emphasized that poor diet resulted in deficiency diseases. Always was visualized and meant the severe acute forms. Up to now growth and prevention of these forms of deficiency diseases have been the inducements to take an adequate diet. But, inasmuch as these severe forms have so seldom been seen, the incentive must have lost some of its edge. Prevention of diseases seldom seen is not a strong incentive to eat proper diet. Our people should be told that their present faulty dietary habits lead most frequently to insidious, chronic malnutrition, often with periodic exacerbations.

Then too; although the necessity of a good diet every day for a lifetime has been taught, it has not perhaps been sufficiently impressed. The gravity of slight dietary deficiencies prevailing for years has not been emphasized. This is understandable since, until recently, ill effects were unrecognized. Now we know that these effects do occur, that they are very widespread, and that they are cumulative over the years. These chronic and slight acute forms, not the severe acute, constitute our malnutrition problem. Since there is likely to be more concern about preventing a strong probability, or almost certainty, than a more remote possibility, there should be more of an incentive to avert the chronic and mild rather than the severe acute states. It is clear that unless an adequate diet is taken continually, these chronic and mild conditions appear. But, as diet educators must realize and point out, it is difficult to adhere to a perfect diet throughout life. They must emphasize that a lapse for a short or protracted period does leave its mark; that because it is so difficult to observe good dietary constantly, deficiency states are extremely prevalent; that a satis-

factory diet must be taken regularly to prevent not only severe forms but more likely the low-grade chronic forms. Or, to put it more simply, an adequate diet must be taken faithfully day after day to insure health.

We must not fail to recognize and admit that under the best circumstances diet education presents difficulties. So insidious is the development of these deficiency states that many persons actually affected with them and manifesting disturbing signs, declare that they feel all right and become aware of their under-par condition only after specific therapy has brought improvement. It is not easy to convince such untreated persons or normal persons of the virtues of a good diet. It is always difficult to preach and promise better health to persons who already regard their present condition, to which they are accustomed, as perfect health. Furthermore, even if such a person is persuaded to better his dietary habits, it is not easy to retain his continued interest. Under the present motivation in diet education, he is led to expect from his changed diet improvements in health which he never realizes or receives.

NEW STRATEGY IN NUTRITION EDUCATION

New strategy in diet education is needed; a new turn should be given to old methods, or entirely new approaches should be tried. I leave the working out of plans and methods to qualified specialists, but I may mention several observations suggesting appropriate and effective lines of action. With accent on youth, on training in proper dietary habits in early years, much more work in the schools is needed. Besides examination system and correction of deficiencies, the curriculum should contain considerable diet education. Second, when coupled with correction of deficiencies by therapy, diet training may be much more effective. Very often

correction by therapy has educational value. It stirs and cultivates interest in diet. When the person experiences the rather prompt benefits in relief of symptoms, he is in a receptive mood for diet education; indeed, he is very frequently activated to seek it. Very often he becomes extremely interested, curious why he was deficient, and is in the proper frame of mind to take his dietary habits seriously. Thus, by utilizing this shift in viewpoint, by fitting it into the program, the effectiveness of nutrition teaching may be greatly enhanced.

Third, the school lunch should be conducted according to dietetic principles. It is with no sense of satisfaction that we learn from surveys that many school lunches are far from satisfactory, and that children who have partaken of them for several years show definite evidences of deficiency states. This raises the question of what may reasonably be expected from the school lunch system. If it is supposed to supply most or all of the day's requirements and to confer complete protection, it is falling far short of the mark. Indeed, that should not be expected, for it is virtually impossible for one meal of natural food, especially a light meal, however carefully planned, to provide the day's needs. If it is supposed to supply what might reasonably be expected in one meal, to be a dependable and potent supplement to the other meals, in short, if it is supposed to supply one good meal a day, no more or no less, in too many instances it is not achieving this more modest and reasonable aim. Its primary purpose should be to serve as a model meal, besides actually supplying part of the day's needs. Through its inculcation of good food habits, the lunch has a place in diet education. But, whatever its function, the lunch system should purvey an adequate meal. To insure this, lunchroom concessionaires should have the benefit of dietary advice and tutelage. Far more lunches are

faulty from ignorance than from greed for excessive profit.

Along with new attempts at diet education, whatever the approach, new or old, we should periodically appraise the methods of application. We should not look for unwarranted approval, especially we should not develop a weakness for panegyrics and fulsome flattery. If our methods are not producing results, we should find it out and change our approach.

Still another point is the proper preparation of food. Of food it may be said as aptly as it was of newspapers, that Greeley made virtue so dull in the *New York Tribune*, while Dana made vice so interesting in the *Sun*. Likewise, a meal scientifically correct in every detail may be a tasteless and unappetizing agglomeration. How many persons have shunned some highly nutritive item because at first encounter it was improperly prepared? Of no less importance in the preparation of food is the retention of its nutritive properties. We are just beginning to realize how severe are the losses in vitamins in foods during their preparation.

It is easy to understand the widespread prevalence of chronic deficiency states when we consider the development of tastes through the centuries for natural foods of limited nutritive value and for refined and processed foods, and the losses in preparation in the home. We come to realize how difficult it is to meet requirements always from usual foods day after day, how easily slight deficiencies are incurred over the years resulting in insidious nutritive changes, how close many persons constantly are to more serious conditions. For protection in these narrow circumstances, we have the possibilities of heavy and exclusive dependence on the absolute effectiveness of diet education in attempting to convert radically the fixed dietary habits in our nation, or the enrichment of certain foods to the point

where compositely they allow a margin for safety. As we ponder the magnitude as well as the serious implications of the situation, it seems highly questionable that we should place sole reliance on diet education. Rather, it seems advisable that we take all available and promising steps. Judicious enrichment of appropriate foods adds much to the guarantee of successful nutrition.

NEED FOR RESEARCH

For protection of youth there should be continuance of basic research on foods, as well as on diagnosis and pathogenesis of deficiency diseases, and their possible predisposing influence to other disease. We must never forget that our present advanced position of enlightenment came from painstaking and prodigious research. In this there must be no letdown in so far as it does not draw upon resources needed more urgently for other purposes in our present titanic struggle for life on a human plane. As a matter of fact, newly discovered facts about nutrition constantly streaming from our research laboratories are of incalculable usefulness in the war effort, as well as for the new world of our making that is to come.

THE ECONOMICS OF THE PROBLEM

Another important aspect of nutrition, especially in the provision of an adequate diet, is economics. Obviously, this problem with its solution is international in scope. It is reassuring to note that our government, alert to both its responsibilities and potentialities of effective action, has made definite headway in this exceedingly complex and intricate field. Following this start, it may be expected that continued careful planning, both on the part of official and unofficial agencies, will be directed toward productive results, not the least of which is benefit to health.

For the whole of nutrition there are needed an attitude, organization, and

program that encompass its many aspects. To achieve joint action, it is necessary to have breadth of outlook, wide-angled vision. It is time to forsake the narrow for the broad view. No other science cuts across so many specialities. By the same token, it requires the concerted endeavor of all. The expert in one branch should not underrate or overlook the strong force which his speciality may exert against malnutrition. Yet, he must not have an exaggerated sense of sovereign powers of his field. I have talked with physicians who have said: "Malnutrition is only an economics problem." Perhaps some economists share that view. On the other hand, by their attitude, some in the health field seem to proclaim that nutrition is only a matter of education. In truth, it is a matter of economics, agriculture, food technology, education, medicine, public health, chemistry, and physics. Its application should extend to all people of all ages and in all activities.

When the branches of nutrition are viewed in their proper perspective, there is no natural rivalry between groups. For example, there is no basis to raise a false issue over food versus vitamin therapy, as if they were alternatives and a matter of choice when actually each has its own particular place in which it is indispensable and irreplaceable. Food industry and drug houses, aside from their own gain, can be more effective in concord than in rivalry. Physicians should not only diagnose and treat, but should seize the opportunity of advancing diet education. Diet experts, besides conducting their educational activities, should take cognizance of the need for therapy for deficiency states. Then too, in the organization for concerted action, no one special group or interest should be supreme, for none could adequately represent all aspects. Until we can find the formula for consolidated action, we cannot expect to bring our tremendous

strength to bear on the problem and to strike with a mighty impact.

Finally, it is not enough to stir willing workers to action if they are not given a plan. For effective results, an aroused spirit and enthusiasm must have sound direction. We must decide what to do and how to do it. Here, above all, we need ideas which are feasible and promise fruitful results. The need to improve

existing nutritive conditions is a challenge to our ingenuity.

In the last few years we have made remarkable progress along the several lines. Never before were we in such a favorable and potent position to carry on effective activity on all fronts. But we have scarcely made a beginning. The nutritional status of our youth will reflect how successful we are in our efforts.

U. S. Chamber of Commerce Organizes Health Advisory Council

The Chamber of Commerce of the United States in Washington announced on February 5 the creation of a National Health Advisory Council to project and carry out a broad program looking to health conservation as an important factor in winning the war.

The National Health Advisory Council will serve to channel approved technical health information developed by the country's sources of scientific study through the business organizations and their members throughout the country so that there may be encouraged a better public understanding and appreciation of medical science as a means of safeguarding public health to win the war.

James L. Madden of New York, N. Y., Vice-President of the Metropolitan Life Insurance Company and Chairman of the National Chamber's Insurance Department Committee, is in charge of the program.

The Council has as its general chairman James S. McLester, M.D., Professor of Medicine at the University of Alabama, Birmingham. Three com-

mittees covering community health, industrial health, and individual health, have as chairmen Wilson G. Smillie, M.D., Dr.P.H., Cornell University Medical School, New York, N. Y.; Leverett D. Bristol, M.D., Dr.P.H., American Telephone and Telegraph Company, New York, N. Y., and James E. Paullin, M.D., Professor of Medicine, Emory University, Atlanta, Ga., respectively. Other persons whose membership in the Council was announced included J. Burns Amberson, M.D., New York, N. Y., George Kosmak, M.D., New York, N. Y., Ernest L. Stebbins, M.D., New York, N. Y., Felix J. Underwood, M.D., Jackson, Miss., Bailey Burritt, New York, N. Y., Henry F. Vaughan, Dr.P.H., Ann Arbor, Mich., Philip Drinker, Boston, Mass., A. J. Lanza, M.D., U. S. Army, Washington, W. A. Sawyer, M.D., Rochester, N. Y., Harry E. Ungerleider, M.D., New York, N. Y., Leroy Gardner, M.D., Saranac Lake, N. Y., Russell Wilder, M.D., Rochester, Minn., Marion G. Howell, R.N., Cleveland, Ohio, and Harold M. Marvin, M.D., New Haven, Conn.

Attitude of the Nation Toward Immunization Procedures^{*}

A Study Based on a Public Opinion
Poll Made in 1941

LEONA BAUMGARTNER, PH.D., M.D., F.A.P.H.A.

Director, Bureau of Child Hygiene, Department of Health, New York, N. Y.

IT is well recognized that wars always increase the hazard of spread of communicable disease. In the present one, in which civilians are so largely involved, certain conditions productive of epidemics may prevail to a greater extent than formerly. Even in as yet an uninvaded country like our own, mass movements of populations to defense plants add a new hazard to the usual one of bringing relatively non-immune rural populations into army centers. Shortages of medical personnel for our armed forces and civilian population are becoming more apparent daily, so that it is of utmost importance that all needless illness be cut to a minimum.

In the armed forces, active immunization to those diseases for which protection can readily be given is easily accomplished, but no such compulsory measures are practical among civilians. It is, therefore, of great interest to study the attitudes of the public toward immunization. Are they ready for such measures? What do they know of them? Do they know when, how, and against what to be immunized? Some of these questions it is now possible to answer as a result of a nation-wide poll taken in September, 1941.

METHOD

A field staff, well trained in technics of interviewing, presented specific questions on immunization against certain diseases to persons scattered over the entire United States. In selecting those to be interviewed, the usual methods used in conducting such surveys^{*} were employed so that an adequate sample of the total population under consideration was secured. Only the adult white population was sampled. Those interviewed were classified according to geographical location (nine divisions of the country), the size of the community (six divisions, including rural populations), economic level (four income groups), age (two groups), and sex. The percentage distributions of the sample and of the general population were identical for each of these criteria, as can be seen in Table 1.

What Is the Prevailing Opinion Concerning Immunization Procedures?

First, interviewers asked, "In your opinion can a person be prevented from

^{*} The survey was conducted by the Elmo Roper organization, probably best known for the public opinion polls it has conducted for *Fortune* magazine. The samples chosen by them have often been proved to represent adequately the opinion of any group under consideration, and in this study they have tested the reliability of the samples chosen. In no instance have data been presented or conclusions been drawn from any sample in which there was not a sufficiently large number of answers to make the data or conclusions statistically significant, unless so stated in the text.

^{*} Presented before the Health Officers Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

TABLE 1
Distribution of Interviews

<i>Geographical Divisions</i>	<i>Per cent</i>	
	<i>Interviews</i>	<i>Population</i>
New England	6.4	6.4
Middle Atlantic	21.8	21.8
East North Central	20.6	20.6
West North Central	10.7	10.7
South Atlantic	12.8	12.8
East South Central	8.0	8.0
West South Central	9.9	9.9
Mountain	3.1	3.1
Pacific	6.7	6.7
Total	100.0	100.0
<i>Size of Place</i>		
Over 1,000,000	12.6	12.6
100,000 to 1,000,000	17.2	17.2
25,000 to 100,000	10.1	10.1
2,500 to 25,000	15.8	15.8
Under 2,500	8.9	8.9
Rural	35.4	35.4
Total	100.0	100.0
<i>Economic Level</i>		
<i>Class Income</i>		
A—well to do	6.8	6.8
B—upper middle	24.7	24.7
C—lower middle	45.5	45.5

<i>Sex</i>		
Total Women	50.5	50.5
Total Men	49.5	49.5
Total	100.0	100.0

getting ——— by being inoculated or vaccinated against it?" Table 2 shows the relatively large numbers who accept the value of such protective measures for diphtheria, smallpox, and typhoid fever, the three diseases for which public health officials most often advocate artificial protection. Those persons who said they did not believe that the dis-

eases could be prevented by specific immunizations were allowed to make voluntary comments after their "yes" or "no" answers had been recorded. Of those who had answered "no," about 60 per cent believed that, because of immunization, a person will have milder forms of the diseases—indicating an even wider acceptance of the procedures than indicated in the "yes" and "no" answers. An additional 18 to 20 per cent felt it might be effective or help in some cases. Only 9 per cent took the fatalistic attitude that "if you're going to get it you're going to get it." There is, thus, apparently little active *disbelief in* or *resistance to* vaccination or immunization. Still let us not forget that 12 per cent do not know if vaccination will protect against smallpox and that larger percentages do not know of protection against diphtheria and typhoid fever.

Do People Believe These Diseases Are Serious?

Respondents were asked to agree to one of a series of specific statements about the seriousness of each of the diseases, and their answers indicate that they understand the nature of the diseases and believe them sufficiently serious to cause concern. It is interesting that they apparently feel smallpox to be less dangerous than diphtheria or typhoid fever. If a lack of understanding of the nature of the disease cannot seem to be the reason why persons are not immunized, what other factors may prevent their being artificially protected?

Are People Deterred from Securing Protection against These Diseases Because of Any Specific Drawbacks?

Answers to this question showed that, in the minds of most persons, there are no serious drawbacks to immunization procedures, 85 per cent stating that there are none or that they know of none. They seem not to differentiate

TABLE 2
*Opinion of Respondents Concerning Preventive Value of
 Immunization Measure against Specific Diseases*

	<i>Typhoid Fever</i>	<i>Diphtheria</i>	<i>Smallpox</i>

much between the measures which protect against the three diseases, except to feel that vaccination is more dangerous than the others.

It should interest those who are concerned with promoting immunization that only 2 per cent of respondents felt such procedures were too expensive or too much trouble. Nor did a history of previous immunization change their opinions. Those who stated that they had been artificially protected volunteered slightly more information concerning the pain or discomfort involved than those who had not, but in general they saw fewer drawbacks.

Thus, the average white adult in the United States finds no specific drawbacks connected with being protected against these three diseases—and his states of readiness to accept all forms of immunization are strikingly the same. Moreover, when asked, 50 per cent of those who had not previously been protected stated that they might be willing to be. Mothers* of unimmunized chil-

dren were even more willing to have their children protected, for over 80 per cent of them answered affirmatively a similar question referring to their children.

What Do People Know About When to Be Immunized?

The public for the most part seems ready for immunization procedures. Do they know when such action should be taken? An answer may be derived from several of the questions asked respondents in the survey. Those who said they might be willing to be inoculated or vaccinated against diseases they have not had or have not been immunized against were asked, "Under what conditions or at what age would you be inoculated or vaccinated against —?" Results showed that most of these persons apparently think immunization is necessary only upon exposure.

A similar question was also posed to "mothers" who might be willing to have their unimmunized children protected. Here the picture changes somewhat. A large number still believe in protection only on exposure, but more important is the fact that they believe that 6 years of age is the proper time to protect children against smallpox and diphtheria. Only 3 per cent stated that they would have their children protected before 1 year of age. It is discouraging to remember that, both in the 1930 White House Conference Report¹ and

* "Mothers of children" are defined as those persons who are, in fact, mothers plus those persons who, regardless of sex, are guardians or persons-in-charge of children. In the classification "mothers with children under 5 years old" are included the answers of persons with children both under and over 5, while in the class "mothers with children over 5 years old" are included answers of mothers all of whose children are over 5 years of age. It is not possible to state if the so-called "mothers" represent an adequate sample of the "mothers" in the population under consideration, for in this one characteristic the sample interviewed could not be matched. It will be remembered that the sexes in the sample were distributed as they are in the general population (see Table 2).

in the survey of 1928 summarized by Collins,^{2,3,4} it was emphasized that there was a tendency to postpone vaccination until school age. It would appear that educational campaigns may well be directed more specifically to this point in the future.

Those who believed diphtheria could be prevented by immunization were asked questions on how often and when one should be immunized. Twenty-five per cent thought one immunization was sufficient; 38 per cent believed more than one necessary; 36 per cent did not know. Although "mothers of children" were better informed, even 25 per cent of them did not know whether one or more than one inoculation were necessary. Add to this the 33 per cent of "mothers" who believe that one immunization is sufficient, and one sees that 58 per cent of those "mothers" who believe in the value of immunization still would probably not be adequately protecting their children if they followed the information they now believe correct.

Of those who felt one inoculation was sufficient, only 41 per cent thought it should be given at 1 year or less, and 17 per cent did not know when it should be given. "Mothers of children under 5" were much the best informed, 72 per cent giving 1 year or less as the earliest age, and only 6 per cent being uninformed. If persons believed that diphtheria immunization was necessary more than once, they seemed uncertain as to when they should be protected, 28 per cent having no idea at all and the remainder volunteering a wide variety of answers. "Mothers" were again somewhat better informed than "non-mothers."

This lack of specific knowledge concerning when to be protected is also emphasized in the answers to the question, "How long does the protection a person gets from inoculation or vaccination against ——— last?" The largest

number (72 per cent for diphtheria and typhoid fever and 52 per cent for smallpox) stated they did not know. Others stated periods from less than 1 month to the duration of a person's life. Few stated periods in accord with the more or less well accepted time limits set by medical experts.

Thus, if the public is to be expected to request the physician to give specific protection against these diseases at the proper time, a great deal of education must still be done, for persons do not know when or under what conditions they should be immunized.

CONCLUSION

In conclusion, it seems important to recognize any factors which could lead to the immediate immunization of as large a percentage of the civilian population as possible. The following generalizations concerning the attitudes of the adult white population in the United States seem justified from the results of a public opinion poll taken in September, 1941.

1. In general the public is aware of the value of immunization against and of the serious nature of diphtheria, smallpox, and typhoid fever, and sees no specific drawbacks connected with being inoculated against them.

2. Over 50 per cent of those who are in need of protection say they might be willing to be protected.

3. The public is not well informed concerning when or how often to be immunized. The importance of having children protected against diphtheria and smallpox in infancy needs particular emphasis.

4. Persons responsible for children are generally better informed concerning immunization procedures than adults not responsible for children.

5. In general, the public opinion is sufficiently favorable toward active immunization against smallpox, diphtheria, and typhoid fever that public health officials and private physicians can well urge such procedures as a routine practice.

Citizen Support for the Health Officer

EDITOR,

The Plainfield Courier-News

There is a big health job ahead all over the nation. Communities are increasing and expanding health budgets to meet new programs and competent health officials are receiving salaries they deserve. . . .

Now is the time for our City Fathers to consider warnings given over and over again by government officials and medical leaders that dangers are increasing, not only from well known diseases, but from entrance into the United States of strange new diseases. Preventive work, which is the business of the health department, must increase in scope and effectiveness. The health department works to keep individuals from being sick by preventing disease from getting a foothold.

Scientists, doctors, and public health specialists are constantly discovering new effective ways to combat and control diseases, old and new. Our city can utilize their wisdom by giving our health officer a chance to expand actual field work and to expand educational services that enlighten and so protect us.

Already that department has helped the general public to understand and benefit by the protection given by pasteurized milk, cleanliness of food sold in our markets, vaccination, choice of

really nutritious foods, and service of the visiting nurse—to mention a few services we now take for granted.

Last year, Plainfield's general death rate per 1,000 population was 10.0, but Plainfield's infant mortality rate per 1,000 births was 33.2, a jump from 27.1 of the year 1941. Usually infant mortality is considered an excellent gauge of public health. Last year in Plainfield there were 30 deaths of children under one year. The year before (1941) there were 19. Measles, scarlet fever and diphtheria caused no deaths in our city in 1941 or 1942. Cancer caused the death of 60 persons in our town in 1941. Last year's records list 35 cancer deaths. Cancer is evidently far from wiped out.

Obviously splendid work has been done by our Health Department. (How many know that some recent phases of its work are known in public health circles throughout the country and are used as a pattern?) Obviously there will be need for far greater service in 1943. Health services must increase and must be provided for in time of war by allocation of ample funds. This is no time to "wait and see what will happen." It's no credit to a town to have an underpaid health officer and an undersize budget that limits his work—*Courier-News*, Plainfield, N. J.

Variations in Phenol Coefficient Determinations of Certain Disinfectants*

CHARLES M. BREWER, PH.D., F.A.P.H.A.

*Insecticide Division, Livestock Branch, Agricultural Marketing Administration,
U. S. Department of Agriculture, Washington, D. C.*

IT has become customary to gauge the strength of a disinfectant by its phenol coefficient value; and ordinarily the labels of coal tar phenolic type emulsions and similar disinfectants bear phenol coefficient statements to indicate their germicidal efficacy. Unless the label states that some other organism has been used, the phenol coefficient is determined against *Eberthella typhosa*. In the enforcement of the Federal Insecticide Act it is required that phenolic type disinfectants be used at dilutions equivalent in germicidal value against *E. typhosa* to a 5 per cent solution of phenol, i.e., at 20 times their phenol coefficient values. Thus a disinfectant with a phenol coefficient of 5.0 should be used for general purposes at a dilution no weaker than 1 per cent. This regulation is for the purpose of allowing a reasonable margin of safety so resistant and inaccessible organisms will be killed in general practice.

Wright⁶ has shown that different brands of peptones used in the composition of the culture medium will give somewhat different coefficient values. The Food and Drug Administration⁵ method prescribes that the culture medium be made with Armour's peptone

prepared specially for disinfectant testing purposes. This method has become generally relied upon as a means of determining phenol coefficients; and it has been shown that by this method workers in widely separated laboratories can obtain essentially the same phenol coefficient value on different samples of the same preparation.²

In 1940 Petroff and Schain⁴ published data showing that the bactericidal properties of germicides are enhanced with the addition of detergents. Within recent years it has become a very common practice to add relatively small amounts of wetting agents to disinfectants with a resulting increase in their phenol coefficients.

It now has been brought out that the phenol coefficient determination alone may not be an adequate laboratory measure of the germicidal value of disinfectants containing wetting agents. During the past year a group of four disinfectants from different manufacturers were tested in the laboratories of the Agricultural Marketing Administration for another governmental agency. Their phenol coefficients were found to be far above the minimum coefficient specified and well above their professed coefficient values.

When the coefficients of these samples were rechecked by using the organisms from two test cultures—I and II—

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

the results differed from each other. Test culture I gave the results previously obtained while test culture II gave lower coefficients. Both I and II were 24 hour cultures in F.D.A. media inoculated from the same source, the only difference in the media being that the peptone ingredient of culture medium II bore a different lot number, having been purchased about a year earlier than that used for making medium I. The difference between coefficients determined with test culture I and II are as follows:

TABLE 1

Disinfectant	Phenol Coefficients	
	F.D.A. Culture I	F.D.A. Culture II
A	9.5	5.0
B	15.0	4.4
C	17.0	5.5
D	30.0	14.4

Culture I and culture II are the same except that the peptone used in making the media bore different lot numbers.

Repeated tests showed that the two test cultures possessed the same resistance to phenol. Against alcohol test culture II showed a slightly lower resistance. No difference in the microscopic appearance of the organisms could be observed. The plate count was approximately equal when salt solution was used to make serial dilutions but test organism I showed a greatly reduced count compared with organism II when serial dilutions were made with water.

Disinfectant B was subjected to further study. When six other strains* of *E. typhosa* were cultured in medium I and medium II and used as test organisms against disinfectant B, the respective divergence of phenol coefficients were comparable to those obtained with the Hopkins strain initially used.

It was thought probable that this group of disinfectants contained wetting

agents which were responsible for the peculiar variation in their phenol coefficients. Consequently two synthetic detergents* (Tergitol, Carbide and Carbon Chemical Corporation, and Vatsol, American Cyanamide and Chemical Corporation) were added in 0.1 per cent amounts to the phenol dilutions tested against test cultures I and II. In the presence of both of these wetting agents the test organism from culture medium I was killed by the higher dilution of phenol. With 0.1 per cent Tergitol present, a 1-125 dilution of phenol killed test organism I in 10 minutes while a 1-100 dilution was required to kill test organism II; 0.1 per cent Vatsol decreased the concentration required to kill *E. typhosa* from 1-90 to 1-160 in the case of the former test culture and to 1-140 in the latter. In the concentrations used neither of these detergents was germicidal for *E. typhosa*. It appeared very definite therefore that some compound of the nature of synthetic detergents was an ingredient of the disinfectants and responsible for the difference in their germicidal action against the two test cultures.

When washed organisms from test culture I were suspended in sterile medium II the same coefficient value was obtained as when washed organisms from culture II were suspended in medium I. Against these resuspended organisms disinfectant B showed a phenol coefficient of 6.6 compared with 15.0 for culture I and 4.4 for culture II. From this it would appear that the peptone in culture medium II contained some ingredient not contained in the peptone of culture medium I which counteracted the enhancing properties of wetting agents; and imparted this quality to the typhoid organisms cultured in it.

* Kindly supplied by Dr. F. W. Tilly, Bureau of Animal Industry, U. S. Department of Agriculture.

* Obtained through the kindness of Dr. H. L. Cupples, Division of Insecticide Investigations, Bureau of Entomology, and Plant Quarantine, U. S. Department of Agriculture.

Baker and coworkers¹ found that phospholipids from various sources inhibited the action of synthetic detergents. Consequently the phenol coefficient of disinfectant B was determined with test culture I in the presence of soluble lecithin as well as Brain Liver Heart Medium (Difco). Added on the basis of 0.1 per cent brain (0.25 per cent complete medium) this preparation reduced the phenol coefficient of disinfectant B to 5.5 while 0.1 per cent lecithin reduced the coefficient to 6.6 and 0.2 per cent lecithin brought the coefficient to 4.0. With either of these sources of phospholipid added to phenol enhanced with wetting agent, the concentration of phenol required to kill test culture I was increased to the concentration required to kill test culture II.

Test cultures I cultured in medium I to which had been added 0.1 per cent lecithin or 0.25 per cent Brain Liver Heart Medium (Difco) reduced the coefficients of all four of the disinfectants below the coefficients obtained with test cultures from the unaltered medium. The results are shown in Table 2; results with test culture II are added for comparison.

TABLE 2
Phenol Coefficient

Disinfectant	Test Culture I	Test Culture 1-A	Test Culture 1-B	Test Culture II
A	9.5	5.0	4.0	5.0
B	15.0	4.0	7.0	4.4
C	17.0	6.5	7.0	5.5
D	30.0	11.0	16.0	14.4

Test culture 1-A is F.D.A. medium culture I plus 0.1 per cent lecithin

Test culture 1-B is F.D.A. medium culture I plus 0.25 per cent Brain Medium (Difco)

NOTE: By using the current lot of prescribed peptone the following phenol coefficients were obtained: A 6.0, B 6.0, C 9.0, D 19.5.

The results of this investigation definitely indicate that one lot of the prescribed peptone for F.D.A. medium contained phospholipid substances lacking in another lot. These phospholipids

are extremely important in the determination of phenol coefficients.

DISCUSSION

Consideration of this report leads to the conclusion that phenol coefficient statements on certain disinfectants containing synthetic detergents are of little or no value. With a determined phenol coefficient of 15.0 for disinfectant B, it might properly be considered a safe general germicide when diluted with 300 parts of water. It was found, however, that a 1-150 dilution of this product failed to kill *Escherichia coli* in 5 minutes and a 1 per cent solution failed to kill pyocyanous (*Pseudomonas aeruginosa*) in 10 minutes. Incidentally a 10 per cent solution of this preparation also failed to kill *Staphylococcus aureus* in 10 minutes. Used according to customary standards, such a product may be valueless as a disinfectant or it may be an effective germicide, depending upon the composition of the peptone used in culturing the phenol coefficient test organism.

The use of peptone with known phospholipid content may become important in the germicidal testing of disinfectants containing wetting agents. However, not all phospholipid substances appear to affect different synthetic detergents alike; and there are many such detergents now available. Cupples³ in 1940 listed over 300 individual preparations of this nature. In connection with the above investigation it was found that added Brain Heart Medium (Difco) was slightly more effective than 0.1 lecithin in lowering the phenol coefficient of disinfectant B when using test culture I; this was contrary to the effect when these enrichment substances were used in the culture medium (see Table 2). Both were approximately equal in reducing the effect of the two detergents added to phenol. But lecithin was much more active than the Brain Heart Medium when added to Zephiran, a surface-

acting compound with high germicidal activity. Zephiran diluted 1-30,000 killed test culture I, and diluted 1-20,000 killed test culture II; 0.25 per cent Brain Heart Medium also reduced its germicidal dilution against test culture I to 1-20,000; but 0.1 per cent lecithin prevented a 1-2,000 solution from killing test culture I in 5 minutes.

The problem of finding a laboratory method for testing the germicidal properties of disinfectants containing synthetic detergents, just as reliable as the phenol coefficient method is for basic coal tar disinfectants, does not appear to be easy of solution.

SUMMARY

Data presented show that the peptone component of the medium for culturing phenol coefficient test organisms may seriously affect the phenol coefficient obtained. This effect on the test culture

is not detectable from the results of the phenol control.

It can be deduced from this investigation that when tested against *E. typhosa* the germicidal activity of disinfectants containing synthetic detergents is greatly altered by the phospholipid content of the culture medium.

Comparative Nutritive Value of Butter Fat and Vegetable Oils*

E. B. HART

Department of Biochemistry, College of Agriculture, University of Wisconsin, Madison, Wis.

SOME 25 years ago¹ it was shown that milk fats were superior to vegetable oils because they contained vitamin A, which was not contained in the vegetable oils. Because of this fact legislation was enacted in various states prohibiting the removal of fat from milk and replacing it with a vegetable oil. In other words, the manufacture of "filled milk" was prohibited by statute in many states, and also by the federal government. Within the last few years those who would like to make a filled milk have learned how they can add vitamins A and D to these vegetable oils and then claim a nutritive value of the product equal to that of milk. By getting out an injunction against the enforcement of the filled milk legislation and prohibiting the enforcement of the law, these companies have succeeded in distributing very considerable quantities of "filled milk." In some states decisions in reference to the validity of the filled milk legislation are pending. In other states licenses are given allowing the manufacture of filled milk, but with an imposed tax.

Now, what is the situation in reference to the nutritive value of butter fat as compared with the vegetable oils? When a vegetable oil fortified with

vitamins A, D, and E is homogenized into skimmed milk to a 4 per cent level and the skimmed milk reinforced with iron, copper, and manganese, there is always an inferior growth of young weanling rats as compared with rats receiving butter fat.² Not only do the rats on butter fat grow better, but they look better; and when kept for reproduction studies, marked superiority in numbers born and reared results.

This growth stimulating property of butter fat lies in the saponifiable fraction,³ since feeding the non-saponifiable fraction with corn oil or coconut oil did not give the results obtained with the butter fat. This superiority of butter fat is not due to a phosphatide or any constituent of a phosphatide, such as choline or choline.⁴ It seems to be due to a saturated acid (or acids) of high molecular weight which is not present, at least in quantity, in the vegetable oils investigated. Hydrogenation of the unsaturated fraction of butter fat results in a product which when added to corn oil gives a growth response superior to the butter fat itself. Hydrogenation of the vegetable oils, such as corn oil, cottonseed oil, soy bean oil, and coconut oil, did not improve their growth promoting properties.⁵

These results make us believe that, in addition to its vitamin A content, butter fat is constitutionally superior to the vegetable oils investigated. This

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

applies particularly in the nutrition of young rats. Similar experiments, however, and similar results with calves have been secured at the University of Minnesota.⁶ Possibly all animal fats are superior for the nutrition of the young to the vegetable oils because of their content of certain essential fatty acids. I do not here refer to the unsaturated acids like linolenic, which prevents what is known as the Burr's disease. These results for the first time show that constitutionally butter fat is superior in the nutrition of a young animal, like a rat, to the vegetable oils investigated. They also make it clear that reinforcement of a vegetable oil with vitamins A, D, and E, will not make it equal in nutritive value to butter fat for the young. These results also make it clear that "filled milk" as at present made, should not be allowed to get into the channels of infant and child nutrition. It may be a healthful food but it shows some deficiencies, just as do many of our staple foods; but where a food becomes the *sole* nutrient of the young, such as whole milk does, then the commercial distribution of an inferior substitute should be prevented.

SUMMARY

Experiments with young rats indicate the superiority for growth of butter fat as compared with certain vegetable oils. This superiority rests upon a constitutional difference and is not related to the differences in vitamin content.

As the sole article of nutrition a "filled milk" in which a vegetable oil has been substituted for the butter fat, based on rat experiments, could give inferior growth with the infant; but no such experiments have been carried out. Until they have and an equality is established, if it exists, the burden of proof of equal value must rest with the purveyor of filled milk, and the public should be protected from a substitute for natural milk.

THE BEVERIDGE REPORT: A SPRINGBOARD FOR THIS EDITORIAL

THAT document which has come to be known as the Beveridge Report (Social Insurance and Allied Services in Great Britain) is now attracting considerable attention and doubtless will continue to interest economists, governments, social agencies, and the medical profession in this hemisphere. In due time, the Report will be reviewed in the JOURNAL. For the moment, it may be said that it sets forth a carefully considered plan, proposed for social security of the people of Great Britain. According to the author, "... the aim of the Plan for Social Security is to make want under any circumstances unnecessary." In relation to medical service, this is said: "Medical treatment covering all requirements will be provided for all citizens by a national health service organized under the health departments and post-medical rehabilitation treatment will be provided for all persons capable of profiting by it." These are bold and forthright statements, clear-cut in their simplicity. They leave no room for confusion as to objective.

The wisdom and applicability of this plan, in its relation to Great Britain, is obviously a matter for Great Britain and only Great Britain to decide. For one in another nation to voice a vote yea or nay would be presumptuous. But in relation to the United States, this Beveridge Report is of particular interest at the moment, for recent news items indicate that the federal government will undertake to provide for the United States a social security plan more inclusive than that which now exists. Inevitably, then, pending announcement of this plan for the United States, and even after that, the Beveridge Report will be scrutinized in terms of its adaptability to the situation in this country. The nature of scrutiny of this document, and of the plan for the United States, will not in all cases be objective and dispassionate. On the contrary, predilections, prejudices, opinions, affiliations, and other conditioning factors will cause many to view all such plans with a jaundiced and tory-like eye; and similar factors will influence about an equal number, out-of-hand, to regard any social security plan as a cross between

the Bill of Rights and the Emancipation Proclamation. Thus there will be those who believe that the bedrock of a successful civilization must rest completely and only upon the full exercise of personal initiative and responsibility and devil take the hindmost, and those who believe that the successful person is, at a minimum, three-fourths rogue, and that the mere fact that a man is down and out is *prima facie* evidence that he is a fine fellow who has been unjustly dealt with.

With these conflicting thoughts, opinions, and interests, it will, of course, be difficult to discover the ideal arrangement, either within the broad field of sociology or in the narrower one of medical care. While it is not probable that the true answer is to be found in an exact middle ground, it is equally unlikely that the solution lies in either one of the extremes. Somewhere in between, to the right or to the left of the center, is the course of wisdom. This wise course is not likely to be reached through an approach giving emphasis to the "rights" of those who have had neither the intelligence nor the integrity to take care of themselves, nor will it include a philosophy that those who have shown initiative and thrift owe something to those who have wasted their opportunities. It will, however, recognize that even in as wealthy a country as this, no inconsiderable proportion of the population is made up of fine American citizens who have been unable to get beyond a bleak subsistence level; that, though possessing initiative and in no way inclined to lean upon others, many millions under the pressure of living have not succeeded in accumulating savings or investments and who, though they have worked faithfully and intelligently within their respective spheres, are not in position to meet the catastrophes of sickness and unemployment. Here the situation exists not because of personal ineptitude or stupidity or slothfulness but rather because of the complexities of a social order to which people of this sort contribute substantially, but from which they receive but meager returns. If there is any logic or strength, or the seeds of permanency in that civilization which created these complexities, it is in all decency obligated to take such measures as may be necessary to offset want and injustice. Families of the sort mentioned, caught in the economic maelstrom, do have rights, and are entitled to social security.

As regards medical service, it seems sensible to conclude that, complementary to private practice, there is need of providing some pooling of resources which will assure good professional care to those who cannot otherwise obtain it. We are not sufficiently an economist to know whether the medical service should be supported by an over-all tax or on an insurance basis. We are inclined to think the latter, but probably hold that opinion because of a desire to avoid being taxed for a service we should not expect to use. If medical care is to be on an insurance basis, it would be necessary, probably, to make such insurance compulsory for those who benefit by unemployment allowances or similar security provisions. Perhaps it should be optional for others. It would be essential, too, so to organize and administer the medical service that it would function on as high a level, and professionally as independently, as a hospital staff. In these opinions we undoubtedly reflect our own predilections, affiliations, and conditioning factors, but we are not naïve enough to think that the matter is as simple as set forth above, nor so inexperienced as to believe that any plan adopted would be free of undesirable elements, deficiencies, and pitfalls. In any event, we believe that if a wise course is to be charted, it is about time that the sane majority of

physicians and the public make themselves heard. This is not a situation which can be benefited either by a blind defense of the status quo or by advocating change for change's sake.

THE ATYPICAL PNEUMONIAS

MORE and more, in medical and public health journals, there are appearing reports of a respiratory infection, or infections, which presents unusual characteristics and unexpected pathology. At present the situation is not clear, but in substance it is this: Clinicians have discovered that many individuals who appear to have only a moderately severe acute upper respiratory infection, prove on x-ray to have a pneumonia. Naturally the severity of illness varies from case to case, but there is general agreement that the results of physical examination are not an index of the underlying pathology; that the patient seems sicker than physical examination of the chest would lead one to expect; that bacteriological investigation does not yield significant findings; that the ordinary chemotherapy of pneumonia is ineffective.

There is no agreement as to how the disease, or diseases, should be designated. Part of this confusion is incident to limitation of knowledge, part of it reflects differences in approach. From a clinical standpoint, the patient presents an unusual condition, and there have thus arisen such terms as "Atypical Pneumonia," "Atypical Pneumonia of Reimann," "Atypical Bronchial Pneumonia," "Atypical Pneumonia with Leukopenia," "Grippe," "Current Bronchial Pneumonia of Unusual Character and Undetermined Etiology," and "Primary Atypical Pneumonia, Etiology Unknown." The last two terms obviously are giving consideration not only to the clinical aspects, but to the etiological. Also from the etiological standpoint other designations are used; "Virus Pneumonia," "Type A Virus Pneumonia," "Acute Infection of the Respiratory Tract, Type A," "Acute Influenza Pneumonitis," "Acute Influenzal Pneumonia." Then on the basis of x-ray findings and underlying pathology, there arise the terms "Pneumonitis," "Acute Pneumonitis," "Acute Interstitial Pneumonitis," "Disseminated Focal Pneumonia," "Benign Circumscribed Pneumonia."

In spite of so many different descriptive titles, there is a tendency to believe that one etiological agent is responsible, probably a virus. As against this hypothesis is the situation in regard to influenza in which there was thought to be a single causative organism, but where further research indicates that at least three distinct etiological agents are involved. Specifically, in connection with causative agents, there has come from the National Institute of Health the report that in a small outbreak of pneumonitis in a group of laboratory workers there was recovered a rickettsia which exhibited the characteristics of a rickettsia previously isolated from cases of "Q" fever. Some time ago, too, the Research Laboratory of the California Department of Public Health reported the isolation of a psittacosis-like virus from two persons who had died of atypical pneumonia; and a more recent paper from the same source indicates that an identical virus was recovered from two cases of atypical pneumonia arising from laboratory infection. A report from another source suggests an association between this

type of pneumonia and a virus which causes pneumonia in cats. Research has been carried out by others, and investigations continue.

Epidemiologic study of so-called virus pneumonia has not progressed as far as is desirable. A deterrent to further advance along this line is the fact that the condition frequently remains undiscovered. In many instances no physician is called or, if called, he may fail to make a correct diagnosis, a failure likely to occur in the absence of x-ray examination of the chest. Finally, it is seldom that even those cases diagnosed come to the attention of the epidemiologist, for few health departments require the reporting of atypical pneumonia as such. The New York City Board of Health has recently made the condition reportable, as doubtless has been done in one or two other forward-looking places. In spite of the lack of knowledge as to causative agent or agents, reporting regulations would seem to be one additional means by which further information may be obtained. It might be well for health officers to give thought to regulations of this sort.

THE YEAR BOOK

This issue of the JOURNAL, for several years, has been supplemented by the *A.P.H.A. Year Book*. Initiated in 1931, and continued in successive years, the twelfth volume, that for 1941-42, will probably be the last for the duration.

The Executive Board has decided to suspend publication of the *Year Book* as an economy measure and as a means of meeting the Government's request to publishers for a 10 per cent reduction in the use of paper.

The JOURNAL will carry from month to month the essential material that has been concentrated in the *Year Book*. A list of Association and Section Committees with their personnel is published in this issue. Next month the Reports of Association Committees presented at the St. Louis Annual Meeting will appear. In May, Committee Reports of one of the Sections will be published as a unit, in June of another Section, and so on until all have been made available. The Committee Reports will occupy the same place in the JOURNAL each month, immediately following the editorials.

Edwin F. Daily, M.D. (1945)
Harold C. Stuart, M.D. (1944)
Leona Baumgartner, M.D. (1943)

PUBLIC HEALTH EDUCATION SECTION

(Organized 1922)

- Edna A. Gerken, *Chairman*, 311 Chamber of Commerce Building, Denver, Colo.
C. Mayhew Derryberry, Ph.D., *Vice-Chairman*, U. S. Public Health Service, Bethesda, Md.
Benjamin G. Horning, M.D., *Secretary*, W. K. Kellogg Foundation, Battle Creek, Mich.

J. Louis Neff (1947)
Thomas G. Hull, Ph.D. (1946)
Carl A. Wilzbach, M.D. (1945)
Clair E. Turner, Dr.P.H. (1944)
Mary P. Connolly (1943)

PUBLIC HEALTH NURSING SECTION
(Organized 1923)

Ella E. McNeil, R.N., *Chairman*, University of Michigan, Ann Arbor, Mich.
Louise Knapp, R.N., *Vice-Chairman*, 416 South Kingshighway Boulevard, St. Louis, Mo.
Marian G. Randall, R.N., *Secretary*, Nursing Consultant, Medical Division, U. S. Office of Civilian Defense, Washington, D. C.
Dorothy Deming, R.N. (1947)
Edna L. Moore, R.N. (1946)

Rena Haig (1945)
Olive M. Whitlock, R.N. (1944)
Bettie W. McDanald (1943)

EPIDEMIOLOGY SECTION
(Organized 1929)

Ernest L. Stebbins, M.D., *Chairman*, Commissioner of Health, New York, N. Y.
Howard C. Stewart, M.D., *Vice-Chairman*, County Health Officer, Franklin, Tenn.
James E. Perkins, M.D., *Secretary*, State Department of Health, Albany, N. Y.
Kenneth F. Maxcy, M.D. (1947)
Dorothy G. Wiehl (1946)
W. Lloyd Aycock, M.D. (1945)
G. Foard McGinnes, M.D. (1944)
Carl F. Jordan, M.D. (1943)

American Public Health Association Committees

1942-1943

Committee on Eligibility

Don W. Gudakunst, M.D., *Chairman*, 120 Broadway, New York, N. Y. (1943)
Reginald M. Atwater, M.D., *Secretary*, 1790 Broadway, New York, N. Y.
Helen Bean, R.N., Public Health Nursing Section (1943)
Martha L. Clifford, M.D., Maternal and Child Health Section (1943)
Mary P. Connolly, Public Health Education Section (1944)
Warren A. Cook, Industrial Hygiene Section (1943)
Godias J. Drolet, Vital Statistics Section (1943)
Thomas Francis, Jr., M.D., Epidemiology Section (1944)
William B. Grayson, M.D., Health Officers Section (1943)
John M. Hepler, C.E., Engineering Section (1944)
Thomas F. Sellers, M.D., Laboratory Section (1944)
Henry T. Scott, Ph.D., Food and Nutrition Section (1944)

Committee on Professional Education

William P. Shepard, M.D., *Chairman*, 600 Stockton Street, San Francisco, Calif. (1944)
Reginald M. Atwater, M.D., *Secretary*, 1790 Broadway, New York, N. Y.
Edward S. Godfrey, Jr., M.D. (1945)
John E. Gordon, M.D. (1943)
Ira V. Hiscock, Sc.D. (1945)
Pearl McIver, R.N. (1946)
George H. Ramsey, M.D. (1943)
Lowell J. Reed, Ph.D. (1947)
Wilson G. Smillie, M.D. (1946)
Ralph E. Tarbett, C.E. (1944)
Clair E. Turner, Dr.P.H.
Henry F. Vaughan, Dr.P.H. (1947)

Consultants:

Walter L. Bierring, M.D.
E. L. Bishop, M.D.
W. S. Leathers, M.D.
John Sundwall, M.D.

Isabel B. Landy, *Associate Secretary*, 1790 Broadway, New York, N. Y.

Educational Qualifications of Professional Personnel in Sanitation

Ralph E. Tarbett, C.E., *Referee*, U. S. Public Health Service, Washington, D. C.

Educational Qualifications of Health Officers

George H. Ramsey, M.D., *Referee*, University of Michigan, Ann Arbor, Mich.

Educational Qualifications of Public Health Nurses

Pearl McIver, R.N., *Referee*, U. S. Public Health Service, Washington, D. C.

Educational Qualifications of Health Educators

Clair E. Turner, Dr.P.H., *Referee*, Massachusetts Institute of Technology, Cambridge, Mass.

Educational Qualifications of Public Health Nutritionists

Pearl McIver, R.N., *Referee*, U. S. Public Health Service, Washington, D. C.

Educational Qualifications of Industrial Hygienists

Henry F. Vaughan, Dr.P.H., *Referee*, University of Michigan, Ann Arbor, Mich.

Educational Qualifications of Laboratory Personnel

Reginald M. Atwater, M.D., *Referee*, 1790 Broadway, New York, N. Y.

Educational Qualifications of Public Health Statisticians

John Sundwall, M.D., *Referee*, University of Michigan, Ann Arbor, Mich.

Educational Qualifications of Public Health Specialists in Maternal and Child Health, in Venereal Disease Control, in Cancer Control, and in Mental Hygiene

Ira V. Hiscock, Sc.D., *Referee*, 310 Cedar Street, New Haven, Conn.

Educational Qualifications of Tuberculosis Directors

Henry F. Vaughan, Dr.P.H., *Referee*, University of Michigan, Ann Arbor, Mich.

Educational Qualifications of Crippled Children Specialists

Henry F. Vaughan, Dr.P.H., *Referee*, University of Michigan, Ann Arbor, Mich.

Educational Qualifications of Public Health Dentists

John Sundwall, M.D., *Referee*, University of Michigan, Ann Arbor, Mich.

Subcommittee on Educational Qualifications of Executives of Voluntary Health Agencies

George J. Nelbach, *Chairman*, 105 East 22d Street, New York, N. Y.

BOOKS AND REPORTS

Trichinosis Problem in California
—*Report of a Survey, 1940-1941*—K. B. Kerr, Sc.D., *State of California Department of Public Health in Cooperation with the U. S. Public Health Service*, 1942. 37 pp.

This pamphlet presents information on the sources of hogs slaughtered in California, the incidence of trichinosis in these hogs, the character of the food which was fed to them, the type of trichinous pork products and their degree of infection, percentage of cases of human trichinosis, and the reported sources of infection of human cases in California. As in surveys previously made in other states, this survey demonstrates the high incidence of trichinosis in garbage-fed hogs (6.4 per cent or 50 per cent of all trichinous pork sold in California). Fresh sausage was the most usual pork product infected, but one sampling of pork chops was found with live trichinae. Cooking of garbage from municipalities before feeding to swine is recommended as a corrective. The report is documented with eleven tables, two maps, and one chart, and has nineteen bibliographic references.

ERNEST CARROLL FAUST

Rockefeller Foundation, International Health Division—Annual Report, 1941—*New York (49 West 49th Street)*, 1942. 224 pp.

To a large extent this report of the International Health Division is a well considered review of the prospects which the future holds for public health. It should be informative to workers in our field to learn where the areas of great potential discovery seem to lie. These reports of studies in yellow fever, influenza, rabies, virus studies, typhus fever, malaria, syphilis, tuber-

culosis, diphtheria, mental hygiene, and nutrition show something of the breadth of the field and indicate where there is hope for more light. Once again the report represents more than an account of stewardship. It is a source of factual information rivalling in its range any other abstracts of research conducted around the world. Presented here in succinct form, it is well worth the thoughtful reading of everyone who wishes to be abreast of the developing science of hygiene.

Of the total of \$72,565,000 spent by the Foundation for public health since 1913, \$18,519,000 has been spent for the control and investigation of specific diseases and deficiencies; \$6,782,000 for aiding state and local health services; and \$6,469,000 for the education of health workers. Buildings, equipment and endowment given for public health represent more than \$22,000,000. Never before in the history of the world has there been such an outpouring of generous help and good will. To a large extent this organization has set the pattern for the more liberal grants now being made by governments in many countries. Without such preparation as this during the last 30 years it would be impossible now to find the human resources to operate the present expanded programs. The public health professions are deeply in debt to the Rockefeller Foundation. REGINALD M. ATWATER

Heredity, Food, and Environment in the Nutrition of Infants and Children—*By George Dow Scott. Boston: Chapman and Grimes*, 1942. 778 pp. Price, \$5.00.

Another "nutrition" book has been written. The first three hundred-odd pages discuss in a reminiscent and

rambling way such matters as heredity, mating, cells, disease, and diagnosis, among other topics. The sections on genetics have been quite ably scoffed at by another reviewer (*J. Heredity*, Sept., 1942). When Dr. Scott finally gets around to his subject the reader, if he has read that far, can only guess what will come next.

Among examples of what might be called "rambling" are such statements as this one (from p. 321, *Pertinent Facts in Infant Feeding*): "Could science in the *past* have controlled *preceding* generations by modern medical methods, fewer dysfunctions from parental syphilis and from other toxins might have been transmitted, fewer alcoholic or sexual excesses might have occurred to darken the lives of so many succeeding little innocent children." (Italics ours.) Or take this one (from p. 323): "Food, plant, and metal poisons in *lethal doses may counteract* beneficial tendencies (to cure of nutritional diseases)." (Italics ours!) By now the reader will have concluded that the author is a master of the qualified statement.

In the remaining 450 pages, 130 are devoted to what is called "Physical and Psychic Stimuli," including such matters as massage, hydrotherapy, baths, sex attraction, and clothing, four kinds of climate, and music, to name only a few of the diverting topics.

In the chapter headed, "Fruits" there is a 17 page cookbook including a recipe for fish in jelly and one for snert (pig's feet).

The book has no index, but only a table of contents. A bibliography occurs after each chapter and is not alphabetized. CARROLL E. PALMER

First Aid. Surgical and Medical
—By Warren H. Cole, Charles B. Puestow and 17 other medical authorities. New York: Appleton-Century, 1942. 374 pp. Price, \$3.00.

Drs. Cole and Puestow have collaborated with several of their colleagues on the University of Illinois College of Medicine Faculty to produce this very useful book on a timely topic. First Aid, it appears, is the most currently popular subject in the field of health education—more than 4½ million people have taken the standard Red Cross course in the last three years!

The book is primarily directed toward the person with a background of knowledge in the biological sciences, especially medicine. The treatment of topics is sufficiently versatile so that physicians, medical students, and nurses will find it of interest and practical value. Many non-medical public health workers can likewise study it with profit.

The greater part of the text is devoted to emergencies relating to accidents caused by war, although emergencies encountered in peacetime have not been neglected. Coverage of such topics as the emergency treatment of wounds, burns, hemorrhage, and shock is especially clear and to the point. A description of blast shock, a potential civilian hazard in World War II, will bring this subject to the attention of many readers for the first time. Definitive or long-range care is touched upon in discussions of first aid treatment, thus lending further interest to the individual subjects. The use of the sulfonamides is alluded to frequently.

The illustrations, which were produced under the auspices of the medical school's Illustration Studio, are decidedly helpful.

The authors feel that first aid training should be part of the individual's liberal education, a principle with which all health workers will agree.

The book can be heartily recommended to all public health workers regardless of whether they are trained in the medical sciences or not.

MILTON ROSE

Aftereffects of Brain Injuries in War, Their Evaluation and Treatment, the Application of Psychologic Methods in the Clinic—By Kurt Goldstein. Foreword by D. Denny-Brown. New York: Grune and Stratton, 1942. 224 pp. Price, \$4.00.

During the World War of 1914–1918 a number of hospitals for the study and care of cerebral injuries were set up in Germany. Kurt Goldstein had charge of one of these institutions. As a result of his experiences he realized the necessity for certain technics of examination and methods of training in rehabilitation, which were previously unknown in the clinic. Fortunately, associated with him was an experimental psychologist, A. Gelb, well trained in psychological methods, with whom technics for functional analysis of behavior were developed. Although Goldstein has described these procedures in some detail in German periodicals, they have not been widely read by clinicians to whom they should have a special appeal at the present time.

The book is divided into two sections, the first dealing with symptomatology and the second treatment. In the first part the author presents a sketchy review of the neurological signs and symptoms following head injuries. The mental aberrations are then discussed in greater detail and the methods which may be used to bring out the defects in the higher mental functions are described. This portion of the book is of particular value to the student of the nervous system, who so often is unacquainted with the tools by which mental impairment may be measured and who using malapropos tests concludes erroneously, that the higher mental functions are intact.

In the second half of the book the treatment of these cases is discussed. Although the therapy is presented clearly and based upon sound psychological principles, the individual meth-

ods of training are largely outmoded due to the rapid advances in the past decade of radio electronics and cinematography. The concluding chapter discusses the problem of social adjustment, which from the patient's standpoint is of paramount importance. Goldstein's statistics on the rehabilitation of patients suffering from cerebral lesions is interesting. Twenty per cent became practically normal workers, 62 per cent were able to do some type of work but below normal capacity, and 18 per cent were unable to pursue any type of painful occupation.

The book is a clear presentation of the problem of the care and rehabilitation of the cerebrally injured, which should be of interest to psychologists, neurologists, neurosurgeons, psychiatrists, and clinicians in general. The bibliography is a valuable although incomplete list of the publications on this subject with particular emphasis on the German literature.

A. EARL WALKER

Ambassadors in White — By Charles Morrow Wilson. New York: Henry Holt, 1942. 372 pp. Price, \$3.50.

This is a book for the man in the street who seeks a general impression, a vivid suggestion of the facts without particular concern about the accuracy or refinement of details. It is a journalist's contribution to the new national interest in the 120 millions or so of neighbors below the Rio Grande.

Of the fourteen chapters, half are devoted to a wholly laudable hero-worship of men of various nativities, but all medical disciples, and each worthy of all praise for his practical services to Latin America.

The first two chapters, "Sick Man's Society" and "Past and Present," may well be required tourist reading for post-war sea-going travellers. Our own Puerto Rico should have taught us

continentals of the States the meaning of centuries of neglect by incompetent governments, essential poverty developed by absentee landlordism, and pervading ignorance without the relief of even the most elementary schooling until recently.

Disease in mass is well illustrated by word, by story, by statistics. The answers to the prayer for prevention are known and can be made effective when commerce, government, and the church combine to provide the men of science with the support needed.

Such a title as "Fierce, Deep, Black Mysteries" is heavily charged only for the quite uninformed physician or nurse or health officer of today, being a series of sketches of diseases fortunately not common in temperate zones.

"Damn the Mosquitoes" and "Banana Medicine" are catchy headings and appeal to the reader who has a bit of spare time to refresh his memory of insect and other pests.

A breezy, well illustrated book which, it is hoped, will carry conviction to the reader who sticks too close at home, or makes travelogues his hobby and wants to know more about Central and South America right now.

HAVEN EMERSON

Contraception and Fertility in the Southern Appalachians—By *Gilbert W. Beebe*. Baltimore: *Williams & Wilkins*, 1942. 274 pp. Price, \$2.50.

The most recent definitive analysis of the effect of contraception on group fertility is Mr. Beebe's study of a service established in Logan County, West Virginia in 1936. This service, unlike those designed to serve women who need contraceptive advice for medical reasons, was a frank attempt to reduce fertility in a region of excessive population pressure.

Contraceptive jelly was distributed to women desiring to try it by a public health nurse who made home visits in

coal mining camps. The first patients were referred by physicians in the county, who gave the project their whole-hearted approval. Other women, who heard of the service, were glad to avail themselves of it, and at the end of three years about 1,300 women had been enlisted.

Mr. Beebe's book begins with a discussion of the economic and social characteristics of the people in the area and an analysis of their fertility before the service was established. His study of the selective factors operating among women accepting advice constitutes a new and very valuable contribution to the field of study. The collection of data on a random sample of women who refused the service, as well as of those who accepted it, substantiates the long existing "hunch" that women who seek or accept contraception are mainly those who have been unable to control their fertility satisfactorily.

On the basis of this information, Mr. Beebe has been able to measure not only the impact of the service on the fertility of the women accepting contraceptive advice, but also to estimate the total reduction in county fertility achieved by this type of service.

Mr. Beebe is convinced that rural services such as the one studied should be instituted under the supervision of official public health agencies. The final chapter discusses the problems of organization and costs in detail, and should be of special interest to public health administrators.

REGINE K. STIX

Civilian Health in Wartime—By *Francis R. Dienaide, M.D.* Cambridge: *Harvard University Press*, 1942. 328 pp. Price, \$2.50.

Interesting and informative, this book will be thoroughly enjoyed by professional workers and laymen alike. Public health in its broad aspects is surveyed

and the whole related to present-day health organization. Recently established governmental agencies are noted in relation to the fields of their activities. As the title implies, the impact of war on health receives key consideration, but only after a firm foundation was laid by accurately describing health conditions as they were before the onset of this war. For instance, the health phases of "aging and the aged" are only a part of that important problem, and the author rightly places particular emphasis on how to fit our fathers and mothers into the scheme of living which is changing so rapidly. This type of consideration is characteristic of the treatment of such subjects as "Shelter and Raiment," "Occupation and Recreation," "Mental Calm and Vigor," as well as the more traditional subjects of nutrition, infectious diseases, and maternal and child hygiene.

One unimportant error came to my attention. Endemic typhus was first diagnosed in the United States in 1913 rather than in 1928.

WILTON L. HALVERSON

Medical Parasitology—By James T. Culbertson. New York: Columbia University Press, 1942. 250 pp. Price, \$4.25.

The author presents, according to his statement, a brief description of the animal parasites and the diseases they cause. The book is divided into two parts. It has an introduction which includes a discussion of the historical aspects of parasites and a definition of terms. Part one is concerned with the general considerations such as infections, epidemiology, natural resistance and acquired immunity, diagnosis, specific therapy, and prophylaxis.

The second section discusses the various parasitic diseases and each parasite is described as to its geographic distribution, morphology, life cycle and cultivation, epidemiology, pathogenicity,

immunity, diagnosis, specific therapy, and prophylaxis.

Since the author has discussed the field of parasitic diseases in a book which is confined to 250 pages of text, he of necessity has had to be quite didactic in certain places with regard to the description of some of the parasites especially *Endamoeba histolytica*. Also, in connection with the treatment of amebiasis, the author expresses the opinion that yatren is the drug of choice and that this drug is effective in the treatment of amebic abscess of the liver. He does mention carbarsone as being less extensively employed. At the present time carbarsone, in the opinion of the reviewer, is the drug of choice for the treatment of amebiasis. It should also be stated that no drug given by mouth has proved to be effective for the treatment of liver abscess. No mention is made of diodoquin in the treatment of amebiasis. This drug is reported to be effective in that condition.

In connection with malaria it is stated that sporozoites enter the red blood cells within an hour or so. This is a point that up to the present time has not been determined. The statement is made and it is implied that malaria therapy will cure neurosyphilis. While this is not a book dealing with syphilis, such a statement is misleading since malaria therapy alone is usually not sufficient to cure this disease. Mention is also made of *P. falciparum* for this purpose. In the opinion of the reviewer, *P. falciparum* should never be used for purposes of inducing malaria as a means of treating neurosyphilis. In connection with the use of atabrine in the treatment of malaria, attention should be called to the fact that this agent is not very effective against the gametocytes of *Plasmodium vivax* and *P. malariae*.

In the discussion of immunity in malaria it is said that man loses his acquired immunity and resumes his normal susceptibility when the malaria

parasite is removed from the body. The opinion as to this point is that immunity in malaria is a strain immunity. If an individual has been infected with a certain strain even though the parasite cannot be demonstrated, there is a relative amount of resistance to that strain upon reinfection.

In the discussion of trichuris, in addition to man as a host for this parasite, it should be stated that it is also found in monkeys, dogs, pigs, and other animals. The clinical manifestations associated with this parasite are discussed and while they may be present in some cases of trichuris infestation, they probably would not represent the usual situation.

The filariform larvae of *Strongyloides stercoralis*, are described as unsheathed. Filariform larvae are usually sheathed. In the discussion of the symptoms associated with hookworm infestation "bloody stools" are mentioned. In the experience of the reviewer, this is a most unusual occurrence.

No mention is made of the use of cellophane swab (N.I.H.) in the diagnosis of *Enterobius vermicularis*. This has proved to be the most efficient method of diagnosis of this parasite and has been of great value in studying the epidemiology of enterobiasis.

In a discussion of morphology and life cycle of *Ascaris lumbricoides* no mention is made of unfertilized ascaris eggs. This form of ascaris egg appears frequently in light ascariasis infestations which comprise a reasonable proportion of most of the cases of ascaris.

In discussing the tick, *Amblyomma americanum*, the statement is made that it does not transmit any infectious agent. It is now known that this tick can transmit tularemia and recently it has been demonstrated as a vector of Rocky Mountain spotted fever.

For a book which has been reduced in size and which covers the large amount of material and which is meant

for a brief discussion of parasitic diseases, it serves a good purpose. It has sixteen figures and seven tables, the latter are quite valuable in setting forth in tabular form the routes of infection, geographic distribution and treatment of the various parasites. There are twenty-one excellent "bled" plates in the book which are unique in a textbook of this kind. There is also an appendix in which there is described the technical methods for the preparation, preservation, and cultivation of materials. This should prove quite useful for technicians and others responsible for such work.

ALVIN E. KELLER

Report of the Committee on Tuberculosis in War-Time — *Medical Research Council Special Report Series No. 246. New York: British Information Services, 30 Rockefeller Plaza, 1942. 36 pp. Price, \$.25.*

This report should be read by every tuberculosis administrator and health officer. It is a concise presentation of the analysis of existing data on tuberculosis mortality in Great Britain and Scotland. It indicates that, between 1939 and 1941, there has been a real increase in tuberculosis deaths in these countries affecting all age groups, children more particularly in recent months, and the older male age groups as well. It is pointed out that there has been some slackening of the rise during the second year of the war, but that the picture is still unfavorable as compared to prewar figures. The committee reports, however, that considering the known course of tuberculosis, further increases must be expected as war conditions continue.

The most acute problem in the present picture is the increased mortality of children from tuberculous meningitis. This is coupled with a serious problem of bovine infection, and the increased danger incident to the large number of adult cases that have

found their way back into the community.

More than half of this report deals with measures for preventing further infection, controlling known cases, and the rehabilitation of known cases. The schemes presented are not new in principle as they are those simple procedures of case finding and supervision which are now well known to all workers in this field. This report, however, has gone further in that it has advocated a broader use of mass radiography than generally practised, and a far more generous financial attitude toward the tuberculous individual and his family during the stage of active treatment and the post-sanatorium period. If we spend large sums to bring a tuberculous case to arrest, we should invest enough to rehabilitate that case to a productive place in society, and this report sees a place in their planning for the chronic case who may have exhausted all known treatment devices without reaching a real arrest of his disease.

This report indicates what may happen in a nation not actually invaded by the enemy, and what should be done about it. It is timely for us in this country for, even though there is no present evidence that there has been a real increase in tuberculosis death rates, the threat is a real one that may be altered by the increased demands on the laborer in industry, the rationing of food, and the environmental problems incident to an all-out war effort. We would do well to adopt most of the recommendations of this report in America today.

HERBERT R. EDWARDS

Mental Illness: A Guide for the Family—By *Edith M. Stern*. New York: *Commonwealth Fund*, 1943. 134 pp. Price, \$1.00.

Doctors and nurses who have responsibility for the recognition and

care of mental illness will welcome this volume with its practical information and guidance for the family. This very readable book has been prepared under the best auspices and can be recommended as reflecting a wholesome and modern viewpoint.

REGINALD M. ATWATER

Elements of Healthful Living—By *Harold S. Diehl, M.D.* New York: *McGraw-Hill*, 1942. 295 pp. Price, \$1.75.

In 1934, Dr. Fishbein suggested that the author write a book on personal hygiene that would be appropriate for the lay public. The author's experience as a university physician and professor of preventive medicine and public health was reflected in a book which was both factual and readable. Written in simple, direct style, it had a wide popular appeal and was adopted as a textbook by many college teachers. Largely at the request of these teachers, the contents and references were enlarged and the book was reëdited as a college *Textbook of Healthful Living*. This book was also well received, but the recent necessity to "streamline" these courses led to requests for a condensed volume. The new edition is a response to the present-day need for an accelerated college teaching program.

The book is limited almost entirely to a discussion of personal health problems though there is one chapter on community health. Special emphasis is placed upon nutrition, mental health, and the various factors contributing to physical fitness. The chapters on major health problems, modern parenthood, health problems of adult life, and choice of a medical adviser, are particularly appropriate. There is a delightful freedom from physiological discussion.

The author has made an excellent selection of material to be retained in the new book, and in no place has he omitted essential information from the text. The deletion of food value tables

in the appendix of the new edition will disappoint college hygiene students who found this an easy and accurate guide. A section on personal hygiene problems related to tropic and arctic living would have served a useful purpose to young men anticipating military service.

Here is a discussion of personal health problems which will meet with popular approval and which will maintain the popularity of its forerunner as a textbook for high school and college students.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Tomato vs. Vegetable Juices—How much ascorbic acid are you getting in your tomato juice or vegetable juice cocktails? The mixed vegetable juices are likely to be inferior in nutritive value to ordinary tomato juice, and there is quite a whale of difference in various brands of the latter. The table tells all.

ANON. Vegetable Juice Cocktails. J.A.M.A. 121, 4:258 (Jan. 23), 1943.

In Place of the Ancient Cooler and Tin Cup—Being the standard of purity for drinking water adopted by the Public Health Service, for use in Interstate Quarantine Regulations of common carriers, this report should have a permanent place in your files.

ANON. Public Health Service Drinking Water Standards. Pub. Health Rep. 58, 3:69 (Jan. 15), 1943.

Doff Your Cap to This One—Methods by which the State of Pennsylvania went about the control of pneumonia, and the salutary results achieved are told in instructive detail. Read, ponder it, and do likewise—or better—administrator!

BORTZ, E. L. Therapeutics of Pneumonia on a Statewide Basis. J.A.M.A. 121, 2:107 (Jan. 9), 1943.

Melancholy Tale—Though it be true that he who lives by the sword may perish by the sword, it is more likely that he will perish by famine and pestilence. This hopeful note ends a gruesome but erudite discussion of the parts played by hunger and disease in molding world history. Don't miss it.

CANNON, P. R. War, Famine, and Pestilence. Sci. Month. 46, 1:5 (Jan.), 1943.

Onset and Duration of Rheumatic Fever—Useful statistics about rheumatic fever should find a preferred place in your reading list. In this paper: age at which the infection usually begins; and mean duration of life for the different beginning age groups.

COHN, A. E., and LINGG, C. The Natural History of Rheumatic Cardiac Disease: A Statistical Study. J.A.M.A. 121, 1:1 (Jan. 2), 1943.

Tuberculosis on a Dollars and Cents Basis—Tuberculosis surveys should include preselection with the tuberculin test, even in the low income groups. The program should concentrate upon the adult population of low economic or social status, providing a chest x-ray for all over 15 who are on relief, and all new relievers, and an annual x-ray between the ages of 15 and 25 for all contacts.

EDWARDS, H. R. The Cost of Tuberculosis Control in the Department of Health, New York City, 1940. Milbank Quart. 21, 1:64 (Jan.), 1943.

Vitamins, Synthetic and Natural—Historians will consider the thirties as the decade of great progress in the chemistry of vitamins; let us hope that the forties will prove to be the decade of sensible application of the available knowledge, hopes the writer of this excellent review of our knowledge of vitamin A alcohol, the vitamin D's, 1-ascorbic acid, thiamin hydrochloride and so on through the list to biotin, and inositol.

ELVEHJEM, C. A. Recent Advances in Our Knowledge of the Vitamins. *Sci. Month.* 56, 2:99 (Feb.), 1943.

Yellow Fever Prophylaxis—Vaccination of adults with a potent yellow fever virus results in an immunity that lasts for at least 4 years—within reasonable but variable limits. In children the immunity is neither as complete nor as lasting.

FOX, J. P., and CABRAL, A. S. The Duration of Immunity Following Vaccination with the 17 D Strain of Yellow Fever Virus. *Am. J. Hyg.* 37, 1:93 (Jan.), 1943.

War-Workers' Midday Meals—Eight valid reasons why it is not an easy matter to improve the diets of industrial workers are discussed in this paper which concludes from reported findings that an active educational campaign is needed by the workers, the employers, and especially the managers of company cafeterias.

GOODHEART, R. Dietary Conditions in Industry. *J.A.M.A.* 121, 2:93 (Jan. 9), 1943.

The Lame, the Halt, and the Blind—Findings of a survey of government industries to discover jobs that might be filled by the handicapped are to be set forth in a loose-leaf manual to aid in the recruiting, training, and placing of those former unfortunates who, because of a wartime man power shortage, will find a chance to lead useful lives.

HARVEY, V. K., and LUONGO, E. P. The Physically Handicapped in Industrial Establishments of the Government. *J.A.M.A.* 121, 2:100 (Jan. 9), 1943.

Something New Under the Sun—Though only a few months old, this painless method of childbirth by means of caudal analgesia will soon be a topic for parlor discussion and back fence gossip. Health workers should be ready with the facts here presented.

HINGSON, R. A., and EDWARDS, W. B. Continuous Caudal Analgesia in Obstetrics,

(and) GREADY, T. G., and HESSELTINE, H. C. Continuous Caudal Analgesia in Obstetrics. *J.A.M.A.* 121, 4:225 (Jan. 23), 1943.

Communicability of Leprosy—Even though you may never see a leper, you will be interested in this brief discussion of the epidemiologic aspect of the disease. Imported infection introduced into the Gulf States shows a tendency to spread. Elsewhere in the United States transmission is so rare as to be negligible from a public health standpoint.

McCoy, G. W. Observations on the Epidemiology of Leprosy. *Pub. Health Rep.* 57, 51:1935 (Dec. 18), 1942.

Representative Vitamin Values—Vitamin A, thiamin, ascorbic acid, and riboflavin contents of two hundred-odd fresh foods, are set forth in a table, especially useful in the coming days of restricted food supplies.

MUNSELL, H. E. The Vitamin A, Vitamin B (Thiamin), Vitamin C (Ascorbic Acid), and Riboflavin Content of Common Foods. *Milbank Quart.* 21, 1:102 (Jan.), 1943.

A Comprehensive Civic Attack on Prostitution—Three excellent ways for *not* controlling the spread of venereal diseases by the harassment, medical control, and health departmental supervision of prostitution serve as a striking preamble to a proposal for the repression of prostitution and the custodial care of prostitutes, which would be unquestionably effective if police and courts would cooperate on a permanent basis with health officials—which they can so seldom be depended upon to do.

NELSON, N. A. The Repression of Prostitution for Venereal Disease Control. *Baltimore Health News.* 20, 1:101 (Jan.), 1943.

To Be Taken Without Grain of Salt—Four down-to-earth papers concerned chiefly with syphilis case-holding and contact-tracing by public health nurses have much in them of interest

to all health workers—if only to convince the skeptical ones that sources of venereal infection really are being traced.

PEARCE, D. Major Public Health Battlefront (and three related papers). Pub. Health Nurs. 35, 1:8 (Jan.), 1943.

Shipyard Eye—You will want to be informed about the findings of this New York study of our newest communicable disease. Prompt diagnosis, meticulous cleanliness and disinfection, strict isolation, and observation of contacts should be helpful in controlling it.

SANDERS, M., *et al.* Epidemic Keratoconjunctivitis. J.A.M.A. 121, 4:250 (Jan. 23), 1943.

Trichinae in Your Diaphragm—Once an outstanding health educator, now a publicist, this writer challenges health officials (in *the* health magazine for the laity) to answer the question: why don't you prevent by legislation the feeding of raw garbage to swine? There is no other way, seemingly, to stop infestation with trichinae which about one in every 6 of us picks up at some time or other.

SHELLEY, M. D. Why Don't We Trim Trichinosis? Hygeia. 20, 12:898 (Dec.), 1942.

Twenty-Five Years at Altro—Sheltered workshops have a useful place in any scheme for the rehabilitation of the tuberculous. As a health worker (especially in wartime) you should be interested in all phases of the rehabilitation of the tuberculous pa-

tient; so you will be helped by reading this account of the Altro workshops.

SILTZBACK, L. E. The Sheltered Workshop in the Rehabilitation of the Tuberculous. Milbank Quart. 21, 1:80 (Jan.), 1943.

After Three Years' Experience—Food handlers examinations are not outstandingly productive in venereal case finding, and cases found are not much of a menace as food handlers (it would cost \$164 for each case of syphilis discovered by this method). Though there is more danger of transmitting tuberculosis through food, that menace is not very great either (it would cost \$503 for each active case so found). As a means of finding typhoid, the method is practically barren of results. The most complete examination could not prevent the spread of acute infections.

SWARTOUT, H. O., and DIERKER, H. Food Handlers' Examinations. Weekly Bull. California State Dept. of Public Health. 21, 49:193 (Dec. 26), 1942.

Competence of the Aged a Matter of Nutrition—Elderly people should start the day with a good breakfast which should include some protein. Refined carbohydrates and fat should be used sparingly. Tea, coffee, and alcohol are useful stimulants. In old age, hunger is less acute and vitamin storage begins to fail, hence added vitamins and minerals are indicated. These abridged morsels are spread before you to tempt you to read this useful paper. You may be old yourself some day—you know!

TUOHY, E. L. Feeding the Aged. J.A.M.A. 121, 1:42 (Jan. 2), 1943.

ASSOCIATION NEWS

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Elmer Belt, M.D., 1893 Wilshire Blvd., Los Angeles, Calif., President, California State Board of Public Health
 Neal D. Carter, M.D., City Health Dept., Wilmington, Del., Commissioner of Health
 David L. Frank, M.D., Battle Creek Health Dept., Battle Creek, Mich., Director, Bureau of Venereal Disease Control
 Roswell L. Hull, M.D., 446 San Benito, Hollister, Calif., San Benito County Health Officer
 Perry W. Jennings, M.D., Canton, Mo., Lewis County Physician and Registrar of Vital Statistics
 William M. Johnson, M.D., P. O. Box 186, Coshatta, La., Director, Red River Parish Health Unit
 Cornelius E. Kline, M.D., M.S.P.H., 5th Avenue Bldg., Moline, Ill., District Health Officer
 Roger G. Knipe, M.D., 4297-10th Avenue West, Vancouver, B. C., Canada, Student, School of Hygiene, Univ. of Toronto
 Hugo Long, M.D., 1 Illinois St., Chicago Heights, Ill., Health Officer
 Franklin J. Malone, M.D., Montgomery County Health Dept., Clarksville, Tenn., Director
 Thomas J. Orford, M.D., C.M., Moose Factory, Moosonee, Ontario, Canada, Medical Officer of Health, James Bay District
 Samuel de la Pena-Mares, M.D., Guadalajara 59-K, Mexico City, D. F., Mexico, Chief, Province de Leche Health Dept.
 E. Neil Reid, M.B., D.P.H., County Offices, Viewforth, Stirling, Scotland, Medical Officer of Health, County of Stirling
 Max Shapiro, M.D., 302 N. Byers, Joplin, Mo., Asst. Health Officer, Jasper County Health Dept.
 Albert H. Williams, M.D., Medical Officer in Charge, U. S. Coast Guard, Air Station, Biloxi, Miss., Asst. Surgeon (R), U. S. Public Health Service

Laboratory Section

Emanuel Appelbaum, M.D., 910 Park Avenue, New York, N. Y., Senior Medical Bacteri-

ologist and Chief, Meningitis Division, New York City Health Dept.
 John W. Bergquist, Ph.M. 2/c, U.S.N.R., Bureau of Naval Personnel, Navy Dept., Arlington Annex, Washington, D. C., Food Inspector, D. C. Health Dept.
 William O. Bolton, D.V.M., 829 South North St., Washington C. H., Ohio, Sanitarian, Fayette County Board of Health
 Lieut. Joe Davis, Sn.C., SCU-1928, Station Hospital, Camp Roberts, Calif., Asst. to the Chief of Laboratory Service, U. S. Army
 Mary L. Forbes, M.S., 512 Shoshone, Boise, Ida., Junior Bacteriologist, State Dept. of Public Health
 Robert B. Gafford, 220½ South Gay, Auburn, Ala.
 John Drennan Hamilton, M.D., Camp Borden Military Hospital, Camp Borden, Ontario, Canada, Officer in charge, Central Laboratories
 Betsy W. Hayes, Perkins Institution, Watertown, Mass., Student, Massachusetts Institute of Technology
 Anne C. Kimball, Ph.D., State Dept. of Health, Minneapolis, Minn., Bacteriologist III, in charge of Diagnostic Serology Laboratories
 Jeannette Buehard Kirby, 612 E. Loren St., Springfield, Mo., Biologist in charge, District Laboratory, State Board of Health
 Harold T. McCarthy, M.S., 215 Lawn Ave., Stamford, Conn., Laboratory Director, Stamford Health Dept.
 Janie F. Morris, M.S., 1041 West Peachtree St., N.E., Atlanta, Ga., Bacteriologist, State Dept. of Public Health
 Sgt. Louis H. Muschel, 4th Service Command Laboratory, Fort McPherson, Ga., Technician
 Walter L. Obold, Ph.D., Drexel Institute of Technology, Philadelphia, Pa., Director of Industrial Biology, Usona Bio-Chem Laboratories, Inc.
 Lieut. Oliver H. Peterson, Sn.C., Station Hospital, Fort Riley, Kan., Bacteriologist, U. S. Army
 Major William Reiner-Deutseh, Sn.C., Station

Hospital, Camp Van Dorn, Centreville, Miss., Chief of Laboratory Service, Army of United States

Alwilda L. Wallace, 123 E. McCarty, Jefferson City, Mo., Bacteriologist, State Board of Health

Vital Statistics Section

Charles G. Bennett, A.M., 4203 Queensbury Rd., Hyattsville, Md., Field Agent, Bureau of the Census

Louis Mesard, M.S., Office of the Surgeon General, War Dept., Washington, D. C., Assoc. Statistician

Engineering Section

John S. Bell, 809 Silas, Sweetwater, Tex., Sanitarian, Sweetwater-Nolan County Health Unit

Joseph H. Coffey, 603 E. Walnut St., Goldsboro, N. C., Area Supervisor, Malaria Control, U. S. Public Health Service

Max J. Colton, C.P.H., 5314 Locust St., Philadelphia, Pa., Assoc. Sanitarian, U. S. Public Health Service

Roscoe H. Goeke, Claremont House, Glenwood Gardens, Yonkers, N. Y., Asst. Public Health Engineer, District 1, U. S. Public Health Service

M. Dudley Johnson, Gulf Health Dept., Edna, Tex., Sanitarian

Frank J. Lindseth, 655 Lake St., Oak Park, Ill., Sanitarian, Oak Park Public Health Dept.

Sidney R. Rebhun, M.S.P.H., 99 Golden Hill St., Milford, Conn., Sanitary Inspector, Milford Board of Health

Industrial Hygiene Section

Lewis J. Cralley, Ph.D., National Institute of Health, Bethesda, Md., Asst. Sanitary Engineer (R), Div. of Industrial Hygiene, U. S. Public Health Service

Alexander M. Riskin, M.D., M.P.H., 1179 Main St., Hartford, Conn., Industrial Hygiene Physician, State Dept. of Health

Steve F. Turner, M.D., 204 Roberts-Banner Bldg., El Paso, Tex., Physician in Charge, American Smelting & Refining Co.

Food and Nutrition Section

Harold K. Cohen, 1326 Holbrook St., N.E., Washington, D. C., Food Inspector and Bacteriologist, D. C. Health Dept.

Capt. Kenneth E. Harshbarger, Second Service Command, Governors Island, N. Y.

Hannah Owen Hutchinson, 806 U. B. Bldg., Dayton, Ohio, Director, The Dairy Council

Maternal and Child Health Section

M. Elizabeth F. Gentry, M.D., Austin-Travis City Health Unit, Austin, Tex., Director of Maternal and Child Health

Irwin Ross, M.D., 190 E. 17th St., Brooklyn, N. Y., Asst. Director (Training and Research), Child Hygiene, New York City Dept. of Health

Margaret M. Scannell, M.D., Court St., Indianola, Miss., Acting Director, Sunflower County Health Dept.

Public Health Education Section

Glenn V. Armstrong, 45 Second St., San Francisco, Calif., Asst. Exec. Secty., California Tuberculosis Assn.

Lester V. Bergman, M.A., 732 Eastern Parkway, Brooklyn, N. Y., The Bergman Associates (production of visual aids for public health)

Irma Biehuse, M.P.H., 310 Cedar St., New Haven, Conn., Asst. Professor of Health Education and Director of Student Health Education, Yale University School of Nursing

Fannie M. Brooks, 703 W. Nevada St., Urbana, Ill., Asst. Professor in Home Economics and Health Education, Extension Service, Univ. of Illinois

Joseph H. Bunzel, 3530 Cottage Ave., Baltimore, Md., Senior Sanitary Inspector, City Health Dept.

Frances T. Dyer, M.A., Isle of Hope, Savannah, Ga., Head, Dept. of Health and Physical Education, Savannah High School

Maribelle Guin, Health Dept., New Bern, N. C., Public Health Educator, State Board of Health

Yolande Lyon, 708 Ellicott St., Buffalo, N. Y., Public Information Secretary, Buffalo Tuberculosis Assn.

Marjorie E. McLean, R.N., 56 Elm, Fitchburg, Mass., Exec. Secty., Northern Worcester County Public Health Assn.

Carl J. Potthoff, M.D., M.P.H., 310 Westbrook Hall, Univ. of Minnesota, Minneapolis, Minn., Assoc. Professor of Biological Science and Preventive Medicine

Everett K. Williamson, 24 E. Market St., West Chester, Pa., Exec. Secty., Chester County Tuberculosis Society

Public Health Nursing Section

Ann C. Barentine, R.N., P. O. Box 652, Charlotte, N. C., Supervisor of Nursing, City Health Dept.

Bertha Harvey, R.N., 1202 W. 3rd St., Davenport, Iowa, Director, Davenport Visiting Nurse Assn.

Ruth E. Jackson, 411 Pennsylvania, Peoria, Ill., Staff Nurse, Peoria Health Dept.

Mary I. McCarthy, 1226 W. Wisconsin Ave., Apt. 609, Milwaukee, Wis., Director of Public Health Nursing, College of Nursing, Marquette Univ.

Lillian O'Callaghan, State Dept. of Public Health, Boise, Ida., State Orthopedic Advisory Nurse

Madeline H. Roessler, R.N., M.A., 2036 S. 6th Ave., Maywood, Ill., Nursing Supervisor, Cook County Public Health Unit

Epidemiology Section

Guillermo Lopez de Nava-Ysunza, M.D., Ave. Colon 804 Pte, Durango, Durango, Mexico Epidemiologist, State of Durango Dept. of Public Health

Claire W. Twinam, M.D., Dr.P.H., Lakeville State Sanatorium, Middleboro, Mass., Acting Superintendent

Unaffiliated

Massimo Calabresi, M.D., 614 Orange St., New Haven, Conn., Student, Graduate School, Yale Univ.

C. Nash Herndon, Jr., M.D., Bowman Gray School of Medicine, Winston-Salem, N. C., Asst. Professor of Medical Genetics

Lawrence Paris, D.D.S., Quoddy Village, Me., Dental Officer, Quoddy Project, National Youth Administration

Byron S. Proper, 17 Battery Place, c/o R. S. Stokvis & Sons, Inc., New York, N. Y., Technical Engineer

George A. Shipman, M.D., 892 Myrtle St., N.E., Atlanta, Ga., Asst. Surgeon (R), U. S. Public Health Service; Industrial Hygiene Physician, State Dept. of Public Health

DECEASED MEMBER

James E. Ives, Ph.D., Washington, D. C., Elected Member 1932—Industrial Hygiene Section

MERIT SYSTEM

Dorothy Adkins, of the Social Security Board, Washington, D. C., has been added to the staff of the Merit System Study to serve as part-time consultant in the field of tests and measurements.

Lillian Dick Long, Ph.D., formerly

of Miss Adkins's staff on the Social Security Board, will serve as Test Technician. Dr. Long has been Instructor in Psychology at Sarah Lawrence College and has been connected with the Office of War Information in New York, N. Y.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

POSITIONS AVAILABLE

U. S. CIVIL SERVICE COMMISSION. Public Health Nursing Consultants, 5 grades. See November *American Journal of Public Health*, or write U. S. Public Health Service, Washington, D. C.

Merit System Council, Oregon State Board of Health and Crippled Children's Division, has announced merit examinations in practically all public health fields. See November *American Journal of Public Health*, or write H. J. Sears, Merit System Supervisor, P. O. Box 88, Portland, Ore.

Indiana State Personnel Division announces that applications may be filed for positions in orthopedic nursing, medical positions (5 classes), and local public health director. See November *American Journal of Public Health*, or write Indiana State Personnel Division, 141 South Meridian Street, Indianapolis, Ind.

Physician, man or woman, as director of Division of Maternal, Child and School Hygiene in southern city department of health. Woman physician with pediatric training preferred, public health experience not essential. To operate prenatal, infant and preschool clinics and promote school health program. Salary commensurate with ability and qualifications of applicant. Apply Box J, Employment Service, A.P.H.A.

Southern state department of health seeks several obstetric and pediatric consultants, requiring a minimum of a year's residency in a specialty, immunity to draft and preferably training in public health. Men and women are eligible. Salary \$300 per month plus travel. Apply Box C, Employment Service, A.P.H.A.

Public Health Engineer and director of Division of Sanitation of a city and county health unit: population 145,000 in the Midwest. Salary \$3,180 and travel allowance. Box E, Employment Service, A.P.H.A.

The Flint Civil Service Commission will consider applications for Executive Health Officer of the Flint Department of Health. Applicants must be medical graduates with a valid license to practise medicine in Michigan or eligibility for such license; also must have practised medicine and surgery for five or more

years and had considerable experience in public health work. There will be no written test, qualifications being judged solely from review of experience, education and training and an oral examination. Present incumbent is on military leave of absence under circumstances which will probably extend for a period of five years. Staff consists of over fifty professional and technically trained employees. Probable salary \$5,400. Inquiries should be directed to Foster B. Roser, Director, Flint Civil Service Commission, City Hall, Flint, Mich.

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, medical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tenn., or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

Public Health nurses wanted for two-county unit in Michigan. Must be graduates with a minimum of 4 months' public health training or 8 months' training under supervision. Salary \$1,800 per year with travel allowance \$35 to \$41 per month. Must drive and own a car. Address Dr. Koupal, Director, Alger-Schoolcraft Health Dept., Manistique, Mich.

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches

of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sanatoria. Open competitive examinations will be held and the resulting lists are expected to be in existence for 2 years or longer. Residence requirements are waived for professional positions.

INDUSTRIAL HYGIENISTS

The Research Section of the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md., needs chemists, physicists, and medical technicians, as well as laboratory assistants in these fields. There is also opportunity for persons without college education, specific training or experience who are interested in such positions. Women now form one-third of the employees in the Research Section.

Wanted: School Dental Supervisor to administer and operate dental program in City schools and clinics in City 50,000 population. Salary \$3,000 to \$3,600 with travel allowance. Those interested should address Dr. W. A. Browne, City Health Department, Alexandria, Va.

Wanted: Chemist and Bacteriologist experienced in the food field for position as director of laboratory operated by national association. Preference given to man familiar with soft drink industry and capable of addressing meetings and writing for publication. Apply in writing giving brief history, references, salary, and draft status. Address American Bottlers of Carbonated Beverages, 1128 Sixteenth St., N.W., Washington, D. C.

The Milwaukee City Service Commission announces an examination for assistant chief in charge of sanitary inspection. Salary first year \$210 per month increasing by \$10 increments annually until a maximum of \$260 per month is reached. Applicants must be citizens of the United States, between 25 and 45 years of age. Those interested may communicate with the Milwaukee City Service Commission, Room 716, City Hall, Milwaukee, Wis.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK, N. Y.

In view of the current active demand for trained and experienced persons in public health it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

M.D., Dr.P.H., interested mental and industrial hygiene, chief of mental hygiene clinic, on staff of psychiatric hospital, speaker, writer, author of books on health, diplomate in psychiatry, professor of psychiatry. Ineligible for military service because of age, healthy, vigorous, able to work hard, now in private practice; would make sacrifice and accept decent but lower remuneration than present income if he could be employed in war industry, preferably New York, New Jersey, or Connecticut. United States citizen. Had important government job

in last war. Speaks and writes several languages. A-504.

Milk sanitarian open for position July 1, 1943. Fifteen years' experience administering and enforcing milk sanitation laws and regulations in midwestern state. References. M-500.

Bacteriologist, 28, Iowa State College, draft immune, 3 years' experience public health laboratory. Experience in investigation and control activities on water, sewage and sanitation, as chemist and bacteriologist and serologist in syphilis and enteric diseases. L-465.

NEWS FROM THE FIELD

URBAN REDEVELOPMENT FIELD STATION ESTABLISHED AT M.I.T.

The Massachusetts Institute of Technology announced recently the setting up by its City Planning Division of an Urban Redevelopment Field Station with funds granted for the purpose by the Albert Farwell Bemis Foundation. Associated in the direction of the Field Station's research program are Professor Frederick J. Adams, head of Technology's City Planning Division, Philip H. Cornick of the Institute of Public Administration, New York, N. Y., and Edwin H. Spengler, Associate Professor of Economics at Brooklyn College and consultant to the National Resources Planning Board. Coöperating agencies include the City Planning Board of Boston, Mass., which has made available to the research group its excellent file of data on physical, economic, and social conditions in Boston, and the American Public Health Association's Committee on the Hygiene of Housing, of which Dr. C.-E. A. Winslow of Yale University is chairman.

One of the important problems now being studied by the Field Station is that of the rehabilitation of urban residential areas where the existing buildings are in sound structural and sanitary condition but where the neighborhood pattern is obsolete. Careful estimates are being prepared of both the capital and operating costs of bringing the environmental conditions in such areas up to a standard in line with modern needs and habits of living, particularly in respect to the planning of the local street system and the adequacy of parks, playgrounds, and other community facilities.

In addition to the municipal costs involved in such a program, studies are also being made of changes in the fiscal

or administrative policies of the local government which might be necessary or desirable if such a program were to be carried out on a city-wide basis, particularly as they might relate to increases in the percentage of tax exempt property and in the costs of maintenance and supervision for a greatly augmented program of neighborhood recreation.

Various proposals for a post-war program of urban reconstruction have been put forward by public and private agencies and it is probable that some scheme involving the participation of federal and local authorities in coöperation with private interests will be adopted as a reëmployment measure when men and materials are again available.

The purpose of the Field Station is to analyze various methods of urban redevelopment which are now receiving consideration with the object of determining their relative value in terms of present-day social and economic conditions.

MEDICAL AND HEALTH STAFF, AMERICAN RED CROSS

The American Red Cross has recently announced the Medical and Health staff as follows:

- Albert McCown, M.D., Dr.P.H., Medical Director, National Headquarters, Washington, D. C.
- Amos Christie, M.D., Assistant Medical Director, National Headquarters, Washington, D. C.
- John F. Busch, M.D., Medical Director, Eastern Area, Alexandria, Va.
- H. E. Kleinschmidt, M.D., Medical Director, North Atlantic Area, New York, N. Y.
- G. Foard McGinnes, M.D., Dr.P.H., Medical Director, Midwestern Area, St. Louis, Mo.
- Milton Rose, M.D., Dr.P.H., Medical Director, Pacific Area, San Francisco, Calif.

EMPLOYMENT OF YOUTH UNDER 18
YEARS OF AGE—POLICY OF THE WAR
MANPOWER COMMISSION

To promote proper utilization of the labor resources of youth with due regard to the welfare of youth and the future needs of the nation, the War Manpower Commission, on January 30, 1943, declared as basic national policy that:

1. School attendance laws and child-labor standards embodied in State and Federal laws be preserved and enforced, and the minimum standard hereinafter listed not be construed to warrant any relaxation of these laws or lowering of the standards embodied in them;

2. No one under 14 years of age be employed full-time or part-time as a part of the hired labor force;

3. Youth under 18 years of age be employed only: after obtainment of proof of age; in work suited to their age and strength; where provision is made for adequate meal and rest periods, sanitary facilities, and safeguards for health and safety; for periods suited to their age and strength, and in no case for more than 8 hours a day or 6 consecutive days, with certain exceptions; during hours of day not detrimental to their health and welfare; and at wages paid adult workers for similar job performance;

4. Youth aged 14 or 15 be employed only when, in addition to the foregoing conditions; qualified older workers are not available; and the employment is not in manufacturing or mining occupations;

5. In-school youth be employed only to the extent that the combined school and work activities involve no undue strain, and that combined school and work hours, at least for youth under 16, not exceed 8 a day;

6. In-school youth not be employed during school hours unless the Area or Regional Manpower Director has determined that temporary needs of an emergency character cannot be met by full use of other available sources of labor, in which case school programs shall be adjusted under plans that provide for the educational progress of those who take employment; avoid interference with the school attendance of those who do not take employment; and avoid the closing of any school or grades therein.

7. In war-time emergency coöperative arrangements between school authorities and employers, the employer to certify to the school authorities that employment will be

in conformity with State and Federal laws and with the standards contained in Sections 3 to 7 above, and the school authorities be responsible for permitting school children to take only those jobs that will contribute definitely to their educational welfare and useful work experience;

8. When young people must be transported to and from work, safe and adequate means of transportation be provided, and the period of work and transportation not exceed 10 hours a day;

9. Where youth under 18 years of age are recruited in groups for agricultural work requiring them to live away from home, prior to placement, assurances be furnished by appropriate community or other agencies that suitable living conditions, sanitary facilities, health protection, supervision, and leisure-time activities will be provided; and in no case youth aged 14 or 15 be recruited for work away from home except where such work is in connection with programs conducted by recognized youth-serving agencies;

10. Any youth interested in work in another area not leave his own area in search of work without first registering for employment locally with the United States Employment Service or another agency designated by the War Manpower Commission; presenting evidence of parental consent; and being referred by such office to a specific job opening where he can be lawfully employed, and where there are suitable arrangements for housing.

RESPONSIBILITY FOR AUXILIARY
HOSPITAL WORKERS

Dr. James A. Crabtree, Executive Secretary of the Health and Medical Committee of the Office of Defense Health and Welfare Services, has announced that it has been decided that it is neither desirable nor practical for the federal government to foster a training program for hospital auxiliary workers. He said that it was felt the problem was entirely local. Some professional groups have contended that the federal government should assume at least partial responsibility for training, placing, and subsidizing auxiliary workers in hospitals, but over a period of months all angles of the proposal have been weighed and the conclusion as announced has been reached.

AWARD TO DR. C. G. KING

The Pittsburgh Section of the American Chemical Society on February 18 awarded to Charles Glenn King, Ph.D., the 1942 Pittsburgh Award "in recognition of Dr. King's outstanding service to chemistry, particularly through his meritorious research and teaching in biochemistry and nutrition." Dr. King is Scientific Director of the Nutrition Foundation, New York, N. Y., and a former resident of Pittsburgh and member of the faculty of the University of Pittsburgh.

INTERPRETATION OF WAR MANPOWER
COMMISSION ORDER CONCERNING
TRANSFER TO ESSENTIAL
INDUSTRY

The *Journal* is informed, through a statement approved by the War Manpower Commission, that individual interpretations of the recent order regarding the transfer of men within draft age to essential occupations have brought apprehension to hospital and health authorities. There is widespread belief among hospital administrators and health officials, it is stated, that the institutions which they represent are not considered essential by the officials of the War Manpower Commission, whereas the contrary is true.

The statement reads in part:

"Several months ago the War Manpower Commission issued a list of Essential Activities, this list to serve as a basis for overall manpower policy, including that of Selective Service. This list of essential services includes 35 broad groups of activities, one of which is titled 'Health and Welfare Services' and includes the following: 'Offices of physicians, surgeons, dentists, oculists, osteopaths, podiatrists, and veterinarians; medical and dental laboratories; hospitals; nursing services; institutional care; auxiliary civilian welfare services to the armed forces; welfare services to civilians.'"

A list of non-deferrable activities and occupations has also been issued through Selective Service designating certain activities in which all occupa-

tions are considered non-deferrable and therefore nonessential. It further designates certain occupations, such as elevator operator, ground keeper, porter and waiter, found in hospitals, health organizations and in nearly all other "Essential Activities," as non-deferrable.

The statement concludes:

"The status of a hospital employee in relation to Selective Service is in no way altered merely by his transfer to some other essential activity, such as aircraft or ordnance production. His status is changed only when he transfers from non-deferrable to a deferrable occupation.

"In summary then, except for the non-deferrable occupations, the position of employees of hospitals and other health services in relation to Selective Service liability is exactly the same as it was before the recent order of the War Manpower Commission."

DR. HARPER RETIRES AS WISCONSIN
HEALTH OFFICER

The retirement of C. A. Harper, M.D., as State Health Officer of Wisconsin was announced in January. Dr. Harper has reached the age of 79 and has been health officer continuously for 39 years, which is said to be a record in such a position in the United States. According to the press, Dr. Harper announced that he had resigned because of less vigorous health and because of a desire to be relieved of some of the details of his position. He will continue in the department as medical specialist in public health. Dr. Harper continues as a member of the Board of Health to which he was first appointed in 1901.

Dr. Harper is a native of Wisconsin, having been born in 1864. He was graduated from the University of Wisconsin in 1889, and received his degree in medicine from George Washington University in 1893. After 10 years of practice in Madison he became State Health Officer in 1904. He was awarded an honorary degree of Doctor of Science by Lawrence College in 1941.

NEW QUOTA FOR NURSES IN TRAINING

According to Paul V. McNutt, Federal Security Administrator, 65,000 young women must enter schools of nursing in the year beginning July 1, 1943, if even the minimum civilian and military needs of the nation are to be met. This exceeds the current quota by 10,000, according to the recommendations of the Subcommittees on Nursing and Hospitals of the Health and Medical Committee, Office of Defense Health and Welfare Services.

Where state nurse registration laws permit, schools of nursing are being urged to contribute to the war effort by accelerating their courses to reduce the usual training period from 3 years to 30 months, and in some instances even a shorter time. In most cases, a college degree subtracts 9 months from the course.

Pointing out that a career woman finds good opportunity in nursing, Alma C. Haupt, R.N., Executive Secretary of the Subcommittee on Nursing, said that she might pursue administration, education, public health, industrial nursing, or any one of a number of hospital specialties.

Federal and private scholarships for nursing education are available. Details regarding these and all phases of student entrance requirements may be secured from the National Committee on Recruitment of Student Nurses, 1790 Broadway, New York, N. Y. Entrance requirements in schools of nursing vary, but in general the following are basic qualifications demanded of an entrant: She must be between 18 and 35 years old, be physically fit, have at least a high school education, and may be either married or single.

RECRUITMENT OF NURSES

New staff appointments to meet more effectively the nation-wide shortage of nurses have been announced by the National Nursing Council for War

Service, which represents the major professional nursing organizations.

Estelle Massey Riddle, formerly Director of the Homer G. Phillips Hospital School of Nursing, St. Louis, Mo., will be consultant on Negro nursing in relation to the war effort. Among her responsibilities will be assistance in recruiting student nurses, counseling with schools of nursing on ways to increase their resources, and recruitment of graduate nurses for military and civilian services. Mrs. Riddle is a graduate of Columbia University and has served on the staff of the Julius Rosenwald Foundation.

Edith H. Smith, formerly Director of the Leland Stanford University School of Nursing and until recently nursing consultant to the Health and Medical Committee of the Office of Defense Health and Welfare Services, will be college recruitment representative, visiting colleges in the eastern states to present the opportunities in nursing before undergraduates, deans, and vocational counselors.

Another new project, that of field service, will soon be set up with the aim of assisting schools of nursing to accelerate their basic course and to make up any deficiencies which might prevent their graduates from being eligible for service with the armed forces through the American Red Cross Nursing Service.

MISS DEUTSCH JOINS PAN AMERICAN
SANITARY BUREAU STAFF

The appointment of Naomi Deutsch, R.N., to the Nursing Staff of the Pan American Sanitary Bureau has been announced. Miss Deutsch will assist the Bureau in South and Central American countries in public health nursing, nursing education, and hospital nursing. Since 1935 Miss Deutsch has been Director of Public Health Nursing for the Children's Bureau, Washington, D. C.

U. S. PUBLIC HEALTH SERVICE FELLOWSHIPS IN HEALTH EDUCATION

The Surgeon General of the U. S. Public Health Service has announced that 20 fellowships providing \$100 per month for 12 months, plus tuition, have been made available through a grant from the W. K. Kellogg Foundation for training at the University of North Carolina leading to a Master's degree in public health.

Pointing out that there is a current need for qualified persons with a thorough understanding of both education and public health, Dr. E. R. Coffey, Assistant Surgeon General in charge of the Division of Sanitary Reports and Statistics, indicates that these stipends will provide for a year's training, 9 months being intramural work and 3 months supervised field experience and he also anticipates employment following successful completion of basic training.

"A candidate for the position of health educator should have not only sound scientific training but good personal health and a pleasing appearance. There is great need for the health educator to have creative ability, leadership qualities, sound judgment, common sense, and adaptability. Since the success of the person in this field depends upon the latter qualifications as well as upon academic achievement, the awarding of the fellowships will be made accordingly.

"In view of the fact that the field of community health education is new, standardized and specific training as a qualification for the fellowships could not be fairly requested. However, it is considered pertinent and important if the candidate is able to present a background including some or all of the following areas of knowledge and skill:

"1. Basic cultural education, including the development of appreciations and skills in the use of the English language.

"2. Basic science education including physics, chemistry, biology, physiology and bacteriology.

"3. Training in education and educational psychology.

"4. Social science education to provide an appreciation of the importance of respect for human personality and government."

The training will begin at Chapel Hill, N. C., March 20, 1943. The summer quarter will be spent in the field. Training ends in March, 1944. Fellowships are open to American citizens between the ages of 19 and 40 inclusive. Minimum educational qualifications include a Bachelor of Science degree, or its equivalent, with major emphasis on basic health and medical sciences, education and the social sciences. Persons interested should apply to the Surgeon General, U. S. Public Health Service, Washington, D. C.

U. S. PUBLIC HEALTH SERVICE DRINKING WATER STANDARDS

The standards of purity for drinking water recommended by the Advisory Committee on Revision of the 1925 Drinking Water Standards, appointed by the Surgeon General in February, 1941, have been printed in the January 15, 1943, issue of *Public Health Reports*, Volume 58, No. 3. Reprints are available from the Superintendent of Documents, Washington, D. C., at 10¢ per copy. Reprint 2440 should be specified in ordering.

The *Journal of the American Water Works Association* reproduces the drinking water standards in its January, 1943, issue. Reprints will not be available from the American Water Works Association.

OFFICERS OF THE SOUTHERN BRANCH, A.P.H.A.

The Secretary of the Association's Southern Branch announces the officers for 1942-1943 as follows:

President, C. F. McClintic, M.D., Charleston, W.Va.

1st Vice President, E. C. Hooper, M.D., Richmond, Va.

2nd Vice President, H. J. Darcey, Oklahoma City, Okla.

3rd Vice President, Donna Pearce, R.N., Washington, D. C.

Secretary-Treasurer, R. H. Hutcheson, M.D., Nashville, Tenn.

COMING VISIT OF BRISTOL, ENGLAND, MEDICAL OFFICER OF HEALTH

On the invitation of the American Public Health Association and the Public Health Association of New York City, British Information Services have announced that Dr. Robert Hughes Parry, Medical Officer of Health of Bristol, England, is expected to be in the United States during March and April and available for public addresses bearing on relationships between public health and the war effort.

Dr. Parry, who was born in 1895, is a graduate of the University of London and has served in experimental pathology in the Bristol Cancer Hospital and as School Medical Officer in Bristol for a number of years. He is professor of preventive medicine at the University of Bristol, and Health Officer of the Port as well as of the city.

It is suggested that state public health associations and other groups consider whether their state programs would permit the appearance of Dr. Parry, whose schedule is being prepared. Those interested should communicate with the Executive Secretary of the Association, 1790 Broadway, New York, N. Y.

EPIDEMIC CEREBROSPINAL FEVER

For the first time since 1929 the reported incidence of cerebrospinal fever during 1942 approached epidemic status. During the year 1942 there were 32 cases reported, with 9 deaths. This was in contrast to the preceding 4 years when the average of reported cases per year was 6. The last major epidemic in San Francisco was in 1929 when there were 88 cases reported with 81 deaths. The history of cerebrospinal fever has indicated that there are periods of high incidence recurring at fairly long intervals.

Increased reporting continues into 1943. During the month of January there were 16 cases reported to the Department of Public Health, of which 2

were listed as non-local. Among the 16 cases there were 2 deaths. Twelve of the cases were males and 4 females. The age incidence showed that 4 were in the group under 5 years, 5 in the group 5 to 20 years, 6 over 20 years, and 1 on which the age was not stated. Fifteen of the cases were treated in hospitals and 1 case was treated at home. As to occupation, 5 of the cases were listed as in the armed forces and 4 reported as shipyard workers.

At the time of this reporting in February the increased incidence appears to be continuing.

PRIZE AWARD FOR RESEARCH ON ALCOHOLISM

The Research Council on Problems of Alcohol, an affiliated body of the American Association for the Advancement of Science, has announced an award of \$1,000 which will be available for outstanding research on alcoholism during 1943, and which is open to any scientist in the United States, Canada, or Latin America. The research for which the award will be granted must contribute new knowledge in some branch of medicine, biology, or sociology important to the understanding, prevention, or treatment of alcoholism. The Committee of Award will consist of a representative of the American Association for the Advancement of Science and four representatives of the Scientific Committee of the Research Council on Problems of Alcohol. Those interested may communicate with Harry H. Moore, Ph.D., Director of the Council, Bronxville, N. Y.

THE KENNY METHOD

Instruction in the Kenny Method for physicians and nurses will be started at an early date at New York University. Information relative to these courses may be secured from Dr. George Deaver, Educational Building, New York University.

DR. CALDERONE APPOINTED DEPUTY
COMMISSIONER IN NEW YORK CITY

Ernest L. Stebbins, M.D., Health Commissioner of New York City, has announced the appointment of Frank A. Calderone, M.D., as Deputy Health Commissioner. He succeeds George T. Palmer, Dr.P.H., who resigned to become the A.P.H.A. Associate Field Director.

Dr. Calderone, who is a graduate of New York University Medical College and received his Public Health Degree from Johns Hopkins University's School of Hygiene in 1937, entered the public health field as Epidemiologist for the New York State Health Department. In 1938 he was appointed District Health Officer of the Lower East Side in New York City, and has been Secretary of the Department since July, 1942. In 1940 Dr. Calderone organized the Mothers Health Organization of the Lower East Side which aroused national interest for its method of enlisting groups of mothers through various community organizations under natural key leaders, and which successfully carried on its own nutrition program. He has been Assistant Professor of Preventive Medicine at New York University. He is a member of the Diphtheria Subcommittee of the Committee on Administrative Practice of the A.P.H.A.

"CURRENT MORTALITY ANALYSIS"

J. C. Capt, Director of the Bureau of the Census, Department of Commerce, Washington, D. C., has announced the publication of Volume 1, No. 1, of *Current Mortality Analysis*, a new publication of the Census Bureau based on the returns of a 10 per cent sample of death certificates received at vital statistics offices. Mr. Capt has announced that, because of the importance in these times of obtaining all information on public health conditions as promptly as possible, the Bu-

reau of the Census has revised its procedure so that certain statistics of national mortality can be obtained many months in advance of the time they were previously available.

The new publication is expected to appear each month approximately 7 weeks after the close of the month in which the deaths occurred. It is especially designed for a limited distribution among persons whose work requires that they keep abreast of public health trends in the United States during the war. It is believed that through this publication public health officials, vital statisticians, epidemiologists, and others concerned with the conservation of man power and the war production program will be able to keep themselves aware of the effect of changes that are taking place in the health environment of the population in various regions of the country. The Census Bureau will honor requests from persons who wish to receive the publication without cost, provided the full title and mailing address are given.

COLONEL RUSSELL TO GIVE BIGGS
MEMORIAL LECTURE

The Committee on Public Health Relations of the New York Academy of Medicine has announced that the Hermann M. Biggs Memorial Lecture will be given in Hosack Hall at the New York Academy of Medicine on April 1, at 8:30 P.M. by Lt. Colonel Paul F. Russell of the Medical Department, Army of the United States, who is the Chief of the Tropical Disease and Malaria Control Section in the Division of Preventive Medicine. His subject will be Malaria and Its Influence on World Health.

The lecture is open to the general public and is in memory of Dr. Hermann M. Biggs, late Commissioner of Health in the New York State Department of Health and a distinguished physician of New York City.

N.T.A. APPOINTS WAR EMERGENCY COMMITTEE

The National Tuberculosis Association, New York, N. Y., has announced the appointment of a War Emergency Committee for the purpose of keeping tuberculosis control programs adjusted to wartime conditions and to plan for post-war control of the disease.

The chairman of the committee is Dr. J. Burns Amberson, Jr., president of the association, and other members are Dr. Harry S. Mustard, director, Delamar Institute of Public Health, Columbia University; Lt. Col. Esmond R. Long, M.D., in charge of the Tuberculosis Section in the Office of the Surgeon General, U. S. Army, who is on leave from his place as director of the Henry Phipps Institute, Philadelphia; Dr. Herman E. Hilleboe, in charge of the Tuberculosis Section, U. S. Public Health Service, and Robert G. Paterson, Ph.D., executive secretary, Ohio Public Health Association.

LAND-FILL GARBAGE DISPOSAL METHOD IN PATENT LITIGATION

The *Public Works Engineers' News Letter* for January indicates that the sanitary land-fill system of refuse disposal practised at New York City has become the basis of a patent infringement suit filed on December 18. The holder of the patents covering the land-fill method, Lewis M. McCarthy of New York City, originally made application on November 6, 1933, and was granted patents on August 4, 1936, and on July 4, 1939, relating to the disposition of refuse by dumping and covering the material with earth excavated from a trench directly in front of the filled area.

New York City has made extensive use of land-fills during the past 6 years, reporting that approximately 11,000,000 cu. yds. of refuse were disposed of by this method in 1941 at an average unit cost of \$0.069 per cu. yd. This cost is

approximately 30 per cent of New York's cost of disposal by incineration. Widespread adoption of the land-fill method at army cantonments has been reported during the past year.

MASSACHUSETTS PUBLIC HEALTH ASSOCIATION

The Massachusetts Public Health Association held its annual meeting on January 28 in Boston electing the following officers:

President, Harold W. Stevens, M.D.

1st Vice President, L. Jackson Smith, M.D.

2nd Vice President, Charles F. Wilinsky, M.D.

Secretary, Raymond S. Patterson, Ph.D.

Treasurer, Elma I. Perkins, M.S.

Executive Committee, Manfred Bowditch, A.B.; Ethel G. Brooks, R.N., B.S.; G. Donald Buckner, S.B.; Roy F. Feemster, M.D.; John W. Williams, M.D.

Representative to the Governing Council of the A.P.H.A., Charles F. Wilinsky, M.D.; (Alternate) Alton S. Pope, M.D.

Representatives to Executive Committee elected by Sections to serve for 1943, Board of Health Section, Vlado A. Getting, M.D.; Laboratory Section, Donald L. Augustine, Sc.D.; Child Health Section, Sallie H. Saunders, M.D.; Food and Nutrition Section, Dorothy Duckles Hudson.

Henry D. Chadwick, M.D., retired as President after two terms. G. Donald Buckner of Worcester retired as Secretary-Treasurer on account of his removal to Worcester to become the Secretary of the Southern Worcester County Health Association. He has served as Secretary since 1934.

DR. FELIX J. UNDERWOOD

The December issue of the *Mississippi Doctor*, the official organ of the Mississippi State Medical Association, carries an editorial dedication to Felix J. Underwood, M.D., State Health Officer, in recognition of the honor that has been bestowed upon him in his election as President-elect of the American Public Health Association at the 71st Annual Meeting of the Association in St. Louis last October.

NEW MEXICO HEALTH CONFERENCE

On January 18 a medical and public health conference was held in Albuquerque, N. M., with participation from members of the staff of the U. S. Indian Medical Service, the New Mexico Third Health District, and the New Mexico Department of Public Health. Emphasis was put on immunization procedures, on sulfaguanadine in treatment of dysentery and on practical application of nutrition, with particular reference to native plants. Dr. Ralph B. Snavelly, District Medical Director for the Office of Indian Affairs, presided.

PAINLESS CHILD BIRTH

A new type of spinal anesthesia has been announced for use in obstetrics, which has been developed by Robert A. Hingson, M.D., and Waldo B. Edwards, M.D., officers of the U. S. Public Health Service stationed at the Marine Hospital at Stapleton, Staten Island, N. Y.

According to the *Journal of the American Medical Association* for January 23, the technic involves continuous caudal analgesia with a solution of metycaine. They report 589 deliveries without maternal mortality and with but three infant deaths, all without reference to the method of analgesia employed.

DR. NEUPERT APPOINTED WISCONSIN
STATE HEALTH OFFICER

Carl N. Neupert, M.D., has been appointed State Health Officer of Wisconsin to succeed Dr. C. A. Harper. He has been a member of the staff of the State Board of Health since 1936. Dr. Neupert was born in 1897, and is a graduate of Washington University School of Medicine, St. Louis, Mo., 1925.

CORRECTION

The attention of the Editor has been called to the fact that the listing of Baccalaureate degrees awarded in public health nursing for the academic year

ending June 30, 1942, by the University of Minnesota as presented on page 1364 of the *AMERICAN JOURNAL OF PUBLIC HEALTH* for December, 1942, and as compiled from figures assembled by the National Organization for Public Health Nursing, is in error. Instead of 378 degrees granted, the figure should be 51.

PERSONALS

Central States

CLIFFORD J. BALDRIDGE, M.D.,† Health Commissioner of the City of Hamilton and Butler County, Ohio, for 20 years, has resigned, effective January 1.

DANIEL C. BARRETT, M.D., C.P.H.,† formerly of Bloomington, Ind., has been detailed by the U. S. Public Health Service to serve as Health Officer of Montgomery County, with headquarters in Independence.

ALLEN A. FILEK, M.D.,† who has been District Health Officer in Green Bay, Wis., has been appointed Director of the Division of Tuberculosis and the Division of Local Health Services of the State Board of Health. He succeeds EDWIN H. JORRIS, M.D.,† who has joined the armed forces.

W. R. GIEDT, M.D., M.P.H.,† formerly Director of Laboratories, South Dakota State Board of Health, Pierre, S. D., was appointed Assistant State Health Officer, October 1, 1942. He succeeds G. J. VAN HEUVELEN, M.D., who entered the Army. Upon the death of J. F. D. COOK, M.D., Superintendent of the State Board of Health, Dr. Giedt was designated as Acting Superintendent until a successor to Dr. Cook is appointed.

SIMON A. KING, M.D., has been named Health Officer of North Dansville, N. Y., to succeed ALDEN J. TOWNSEND, M.D., who resigned to enter military service.

* Fellow A.P.H.A.
† Member A.P.H.A.

GREGORY J. NORDENBROCK, M.D., of St. Marys, Ohio, has been appointed Health Commissioner for Shelby County, effective December 15. He succeeds HARRY WAIN, M.D.,† of Sidney, resigned.

S. L. PEARLMAN, M.D., M.S.P.H.,† P.A. Surgeon (R), U.S.P.H.S., has been transferred from the Health Department of Omaha, Nebr., where he served as Communicable Disease Control Officer to the Health Department of Chicago, Ill., as Director of Venereal Disease Clinics.

HERBERT L. PETTITT, M.D., of Morrison, Ill., who recently resigned as Assistant State Health Director to resume private practice, has been appointed Chief of Emergency Medical Services in the Illinois Defense Council. He succeeds ROLAND R. CROSS, M.D.,† of Springfield, State Health Director. Dr. Pettitt will devote only part time to the position.

ROBERT W. REID, M.D., of Union City, Ind., has been appointed Health Officer of Randolph County, to succeed ANDREW M. BRENNER, M.D., of Winchester, who has entered the Navy.

GARFIELD A. REUTTER, M.D., formerly of Bigfork, Minn., is the new Health Officer of Cherokee County.

Eastern States

W. RODERICK BROWN, M.D., Pittsburgh, Pa., has been appointed to the staff of the Medical Division, Office of Civilian Defense, Washington, D. C., to supervise the training of Negro physicians in emergency medical service for civilian defense. Dr. Brown has been a member of the medical staff of the Tuberculosis League of Pittsburgh and the Chest Unit of the University of Pittsburgh Medical Center.

WILLIAM J. CARRINGTON, M.D., of

Ventnor, N. J., Vice-President of the American Medical Association, has been commissioned a lieutenant-colonel in the Army Medical Corps and expects to take charge of an Army hospital soon.

MRS. INA J. DURFEE, of Dedham, Mass., was appointed Executive Secretary of the Hartford Tuberculosis and Public Health Society, Inc., on January 14, to replace S. DOUGLAS POLHEMUS † who has gone into the Army.

GENE B. HABER, M.D., Passed Assistant Surgeon, U. S. Public Health Service (R), has been assigned to the New Hampshire State Board of Health and is serving as health officer of the Eastern Health District with offices in Exeter, N. H. He replaces EDWARD W. COLBY, M.D.,† who is now in charge of the Division of Epidemiology and Venereal Disease Control at the State Headquarters, in Concord.

DR. HENRY C. SHERMAN, of Columbia University, New York, N. Y., delivered the Mary Swartz Rose Memorial Lecture on February 17 at the New York Academy of Medicine. The subject of the lecture was "The Concept and Practical Significance of Internal Environment." The meeting was sponsored by the Greater New York Dietetic Association.

RACHEL E. SPINNEY, M.S.P.H.,† who has been Health Education Secretary with the Hartford Tuberculosis and Public Health Society, Hartford, Conn., has resigned to accept a position with the Tuberculosis Institute of Chicago and Cook County, Ill., as Director of Health Education.

A. HAMILTON STEWART, M.D.,† of Indiana, Pa., has been appointed Secretary of Health of Pennsylvania, as announced by Governor Edward Martin. Dr. Stewart has served during the last 4 years first as Deputy Secretary then as Acting Secretary and finally as Secretary during the

* Fellow A.P.H.A.

† Member A.P.H.A.

last month of the preceding administration of Governor James.

Southern States

CAROLINE H. CALLISON, M.D.,† of Chatom, Ala., will serve as Health Officer of Washington and Clarke Counties.

JULIUS E. DUNN, M.D., of Florence, Ala., is the new Health Officer of Etowah and Calhoun Counties, with headquarters in Anniston.

JEAN HENDERSON,† formerly Public Relations Consultant with the Florida State Board of Health, Jacksonville, has been appointed Information Consultant to the Health and Medical Committee, Office of Defense Health and Welfare Services, Washington, D. C.

KATHARINE F. LENROOT,* Chief of the Children's Bureau, U. S. Department of Labor, Washington, D. C., was awarded the Rosenberger Medal for "notably great service in the promotion of human welfare," at the University of Chicago on December 18.

PERRIN H. LONG, M.D., Professor of Preventive Medicine at Johns Hopkins University School of Medicine, Baltimore, Md., has received the award of the Southern Medical Association for original work by one of its members. The award was made in recognition of his studies on the sulfonamides.

G. FOARD MCGINNES, M.D., DR.P.H.,* has been appointed Medical Director of the Midwestern Area of the American National Red Cross with headquarters in St. Louis, Mo., effective February 15. Dr. McGinnes is a graduate in medicine of the University of Virginia and in public health from Johns Hopkins. He has served with the Virginia State De-

partment of Health and the State Department of Health of Tennessee, where he recently has been Director of the Venereal Control Division. For several years Dr. McGinnes was Secretary of the Southern Branch, American Public Health Association.

ELISHA MOORE, M.D., of Livingston, Health Officer of Sumter County, Ala., has also been placed in charge of the Greene County Department of Health.

RALPH E. TARBETT,* Chief Sanitary Engineer of the Office of Civilian Defense, has been recalled to the U. S. Public Health Service by the Surgeon General. He will assume direction of the Federal Facility Security Program as it relates to domestic water supplies, responsibility for which was assigned to the Public Health Service by Executive Order of President Roosevelt on May 19, 1942. GORDON E. MCCALLUM, Assistant Chief Sanitary Engineer, has been named to serve as Acting Chief Sanitary Engineer in the Office of Civilian Defense, in place of Mr. Tarbett.

FRANK B. WOOD,† Engineer (Sanitary), with the U. S. Engineer Department, was transferred on January 1 to the office of the Mississippi River Commission and the Lower Mississippi Valley Division at Vicksburg, Miss., from the Vicksburg, Miss., District.

Western States

LT.-COL. GEORGE H. HAM, of Culver City, Calif., has been appointed Base Surgeon at the Army Air Corps Base in Key Field, Miss. He has been located in Washington, D. C., while serving as The Surgeon, of the Ferry Command.

Canada

ADA I. WALLACE, M.D., Medical Health Officer for Emerson and the rural municipalities of Franklin and Mont-

* Fellow A.P.H.A.

† Member A.P.H.A.

calm, was recently appointed first woman Coroner in the history of Manitoba, it is reported.

DEATHS

GEORGE WASHINGTON CRILE, M.D., of Cleveland Heights, Ohio, world renowned surgeon, died January 7, at the age of 78.

DR. LEE HOLLISTER FERGUSON, Director of Health Service for Western Reserve University, Cleveland, Ohio, died January 27.

WILMER KRUSEN, M.D., of Philadelphia, Pa., died February 9. He had served as Director of Public Health of Philadelphia, and became President of the Philadelphia College of Pharmacy and Science in 1927, and was President-emeritus since 1941.

DR. EZRA KIMBALL SPRAGUE, former Medical Director of the North Atlantic District of the U. S. Public Health Service, died February 2, in Brooklyn, N. Y.

The Army's Contribution to Industrial Hygiene*

LT. COLONEL A. J. LANZA, M.C., F.A.P.H.A.

*Chief, Occupational Hygiene Branch, Office of the Surgeon General,
War Department, Washington, D. C.*

WHEN warfare became mechanized and large numbers of soldiers were enrolled in what is termed "The Armored Forces," industrial hygiene came to the Army—Military occupational hygiene.

The mechanization of warfare brought to the soldier, in addition to hazards of combat, certain health hazards which formerly were associated with various types of industry—hazards of fumes, gases, and dust, hazards of maintenance and repair with their job as soldiers in the Armored Forces. Associated with these considerations are those resulting from military activities all over the world necessitating detailed studies of proper rations and proper clothing, and the important matter of water consumption. From the need to know all that could be ascertained about these important items, there was born the Armored Force Medical Research Laboratory at Fort Knox devoted to maintaining and increasing the physical effi-

ciency of the soldiers in the Armored Forces—especially the tank crews. This is one of the most important phases of the application of industrial hygiene in the Army.

Physiologists, physicists, pathologists, ventilation experts, chemists, biochemists, nutrition experts are determining what must be done to protect the health of the soldier in a mechanized war, fought under all varieties of climate. The soldier in many phases of Army life is of necessity a skilled craftsman—a highly trained mechanic. The Armored Force trains thousands of young men in many branches of mechanics, including communications, and in so doing is making a tremendous contribution to the welfare of the nation.

It is the aim of the Army that these men learn their respective skills under the most favorable conditions, and are protected from health hazards both while learning and practising their jobs.

The Army employs not only soldiers but industrial workers, and is now probably the largest employer of labor in the country. The Army owns and

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

operates more than 160 industrial plants, and owns more than 250 industrial plants which are operated under contract. These plants embrace every phase of the manufacture of the munitions of war, explosives and related chemical industries, and the maintenance and repair of mechanized equipment and aircraft. These industrial establishments include many whose employees number ten to twenty and thirty thousand industrial workers, an ever increasing number of whom are women. In all, as nearly as can be ascertained under conditions of rapid expansion, more than 600,000 men and women work in these plants.

Out of the needs created by this situation there was established in the Division of Preventive Medicine in the Surgeon General's Office, an Occupational Hygiene Branch. The functions of this branch are to satisfy the responsibilities of the Army, in its rôle as an employer, to its employees. In this respect the Army is in the same position as any other employer. Working conditions must be safe, unavoidable health hazards must be controlled, environmental sanitation must be enforced, and adequate medical service, of the type that has become standardized in well run American industrial establishments, must be maintained.

In order to fulfil these functions two main activities have been undertaken:

1. Wherever indicated, industrial physicians with the necessary training and experience, have been commissioned in the Medical Corps and assigned to the Army-operated plants. Acknowledgement is here made to the medical directors of American industry whose coöperation has made this course of action possible. Industrial physicians have also been assigned as industrial medical officers to the service commands. Industrial hygiene engineers have been commissioned in the sanitary

corps and have also been assigned to Service Commands and to those establishments where they are needed.

2. There has been established an industrial hygiene laboratory, located in the School of Hygiene and Public Health of Johns Hopkins University. The main function of this laboratory is to study environmental conditions in Army-operated plants, make special inquiries, and elaborate methods of controlling health hazards. Nothing is static. New inventions, new war agents, new manufacturing processes are the order of the day, all bringing their own peculiar problems of health and safety.

In supervising health conditions in the Army-owned, contractor-operated plants, the Surgeon General's Office is most fortunate in having the assistance of the Division of Industrial Hygiene of the U. S. Public Health Service with their vast experience in this field. The medical departments of these contractor-operated plants are not staffed with military personnel but are employees of the company physicians and their assistants. The aid of the Public Health Service makes it possible to carry on a complete program.

The Occupational Hygiene Branch maintains an active liaison with the various Army Departments, particularly the Ordnance Department, the Chemical Warfare Service, and the Air Force, who contribute their technical knowledge and experience to the health problems, often complex, which are encountered.

The progress of industrial medicine and industrial hygiene in this country in the past 25 years has been continuous and has reached a high point of efficiency. It is the aim of the Army to provide the benefits of this progress to both soldiers and civilian employees, as well as to contribute to it out of its own experience.

Industrial Hygiene Program of the U. S. Navy*

REAR ADMIRAL C. S. STEPHENSON (MC), U.S.N., AND
COMMANDER OTTO L. BURTON (MC), U.S.N.

*In Charge, Division of Preventive Medicine, Bureau of Medicine and
Surgery, U. S. Navy; and In Charge of Section of Industrial
Health, Division of Preventive Medicine, Bureau of
Medicine and Surgery, U. S. Navy,
Washington, D. C.*

THE rôle that our government expects all industrial physicians and hygienists to play in the war effort is to institute measures to promote and maintain the health, well-being, and morale of civilians. Such measures should be applied to all classes of population but especially to the industrial workers whose working efficiency is of especial importance.

With industrial establishments being rapidly expanded, and new plants being constructed we will need more and more workmen. Minors, women, retired employees, and workers with physical defects which disqualify them for military service are making our industrial health problems more acute. These groups will have to adjust themselves to more strenuous tasks, more concentrated efforts, and probably longer hours than those to which they have been accustomed. The health of these employees is of paramount importance. The government is depending upon you to institute measures now to prevent any shortage of plant man power due to preventable illness or injury.

It has come to our attention recently

that the employees of a certain firm suggested that rest periods and lunch period be discontinued. They offered to eat lunch while continuing at work. Obviously such a scheme would not be conducive to maximum production. Another plant has permitted apprentices to work 7 days every week in order to shorten the duration of the apprenticeship period. A 7 day work-week is undesirable, regardless of age, is injurious to health, and a threat to the youth of the country.

If we could have assurance that our war effort would be successful in a matter of a few months we could speed up production by long days and weeks and probably get away with it. On the other hand, since we do not know how long we will be in this state, we should eliminate the temporary sprinting and buckle down for a long distance run with our speed regulated to meet the situation.

The Council on Industrial Health of the American Medical Association some time ago prepared an outline as a guide for those interested in industrial medical relationships and the objectives aptly stated were:

1. Prevention of disease or injury by establishing proper medical supervision over in-

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

dustrial materials, processes, environments and workers.

2. Health conservation of workers through physical supervision and education.

3. Medical and surgical care to restore health and earning capacity as promptly as possible following industrial accident or disease.

In recognition of its responsibility for the maintenance of the health of its industrial employees, the Navy for many years has had an active safety program at its numerous shore establishments. In addition to industrial accident prevention it has recognized that the basic principle of health promotion was eminently worthy of consideration. Because of the enormous expansion in naval construction additional problems and exaggeration of old ones had to be coped with. So two years ago the Navy began to enlarge its industrial health program from the nucleus of its existing organization.

We all realize the decisive part industry must play in the present war and that victory will ultimately depend upon surpassing the enemy in producing ships, planes, munitions, and supplies of all kinds with which to support the armed forces.

Adverse working conditions result in industrial absenteeism, and surely this loss of time cripples defense. Efficiency and maintenance of health cannot be divorced. Today industrial efficiency must be measured in terms of military gain or loss. Recently one of the navy yards launched a fine, new capital ship built without a single fatality. That represents a military victory.

ORGANIZATION

1. Section of Industrial Health

The Navy proceeds with the belief that dangerous material can be handled safely and that any mechanical job can be performed safely if proper study is given in advance and the necessary precautions are observed.

Early in 1941 a new Section of In-

dustrial Health under the Division of Preventive Medicine was set up in the Bureau of Medicine and Surgery. The medical officer in charge of this section has been formally trained in industrial hygiene and the fundamentals of safety engineering and also possesses a degree in public health. This section coöperates with the Shore Establishments Division of the Navy Department to conserve the health and prevent disease and injury in Navy industry. It operates in the major areas of industrial hygiene by the establishment of proper control over the industrial environment in navy shore establishments; by analyzing occupational disability reports and making recommendations to the field in regard to detection and elimination of potentially hazardous working conditions; by preparing information on various hazardous materials and processes; and by coöordinating the efforts of the industrial hygiene field personnel.

2. The Field Organization

Over 50 navy medical officers have completed postgraduate instruction in industrial hygiene and many more have developed varying degrees of proficiency through personal experience in the navy industrial shore establishments. Such medical officers have been assigned to navy industrial shore establishments to be in charge of distinct units of industrial hygiene under the Senior Medical Officer. The majority of these officers are putting full time on industrial health work and coöperating with the station safety officer so as to provide and promote an adequate safety and health program.

Each principal industrial station has assigned in addition, one or more officers who are graduates of schools of chemical engineering, sanitary engineering, mechanical engineering or chemistry, and trained in industrial hygiene. These officers are equipped with neces-

sary laboratory and field equipment to help the medical officer in handling problems of dust, fumes, illumination, noise, ventilation, etc.

The functions of the medical officer for industrial hygiene, and those of the safety officer are separate, though closely correlated. The former includes the study of the natural health hazards of occupational activities, the conduct of the necessary technical surveys to determine potential or existing exposures, and the laboratory analyses to evaluate these exposures. These observations and recommendations are made available to the safety officer who is responsible for the application of the necessary corrective measures.

In summary the functions of the medical officer for industrial hygiene are:

- a. To study the occupational health problem.
- b. To determine the toxicological data in terms of their effect on workers.
- c. To conduct surveys of potential health hazards in specific activities and processes.
- d. To collect samples in the field pertaining to occupational health exposures.
- e. To make laboratory analyses both on samples taken in the field and on any material submitted with reference to the causation of occupational disease.
- f. To prepare reports of findings, recommendations and conclusions evaluating the hazard of occupational health conditions.

3. Shore Establishments

The Navy Department Safety Engineer serves as adviser to the Director of the Division of Shore Establishments. This division is under the central administration of the Assistant Secretary of the Navy. The division develops the standards for safety protective equipment used by the navy stations and is responsible for the development of the general safety rules for shore establishments of the Navy. By frequent field surveys the Navy Department engineers, through the Director of the Division of Shore Establishments, serve in a technical advisory

capacity to the field in problems of safety engineering.

At each establishment a naval line officer, designated as the safety officer is responsible for the administration of the accident prevention program. He may be assisted by a junior line officer, a civilian assistant engineer, and one or more civilian safety inspectors. In general, one safety officer, engineer, or inspector is available for each 1,500 employees, which is in addition to shop safety inspectors assigned to specific shops.

The duties of the safety officer include: thorough inspections and general surveys of all mechanical conditions of the working places; the addition of necessary appliances for the protection of employees; and the investigation of all accidents in order to devise means for preventing a recurrence. All improvements come under his supervision. There must exist close coöperation between the safety officer and the Medical Department so as to correlate all phases of the safety problem.

THE INDUSTRIAL HEALTH PROGRAM

The object of the Navy's industrial health program is to protect the health, safety, earning power, and efficiency of the worker, and promote maximum production by minimizing the occurrence of occupational diseases, needless exposure to death or disabling injury, and absenteeism from whatever cause.

All prospective employees are given a complete physical examination by a member of the Navy Medical Corps to determine their physical condition and fitness for duty. The results of such examinations are of great value in proper placement so that the new employee will not constitute an accident risk to himself or others. Frequently correctible defects and incipient disease are discovered and the man is strongly encouraged to consult his family doctor for appropriate treatment. Following

the preemployment examination the prospective employee is told of the importance of reporting to the dispensary for proper care of all minor injuries and the ground work is started in regard to creating interest in safety.

All industrial employees in whom physical defects may endanger the health of themselves and/or others and who are subject to any occupational disease exposure, are given physical examinations at intervals sufficient to insure that necessary precautions are taken to maintain and improve their health and efficiency.

Operators of cranes, locomotives, engines, and other similar work, are given complete physical examinations yearly. Employees with an exposure to silica dust receive a chest x-ray every 6 months. Handlers of radium or radioactive luminous compounds receive a complete physical examination, including analysis of breath for radon, twice a year. Workers cutting or welding painted or coated materials and spraying lead pigmented paint receive a basophilic aggregation test quarterly where proper engineering control is considered in effect. The medical officer and the safety officer collaborate in determining sources of occupational disease exposure at each station, necessitating a periodical physical examination.

First aid boxes are not allowed in shops or offices because experience has shown that employees improperly take care of minor injuries and in many cases serious infection develops which results in loss of time and possible permanent disabilities. Every employee who is sick or injured must report to a first aid station, sub-dispensary, or main dispensary for treatment or advice.

A large factor of medical importance that affects the well-being and therefore the efficiency of workers is the relation of the worker to his environment. Because of the difficulty in obtaining certain strategic materials there is a con-

tinuous search for substitutes, and the Medical Department must stay on guard to anticipate and control possible hazards from new processes and new materials.

It is necessary that the medical officer know what potentially harmful substances, conditions, or forms of energy are being used, to what degree and the length of exposure in case of each individual or group before such harmful contaminants can be controlled.

Analyses to determine the presence and quantity of fumes, gases, and chemicals, and the sound application of hygiene, sanitation, and accident prevention, with periodical physical examinations are essential to the general plan of providing a safe and desirable working environment.

An industrial hygiene laboratory, adequately equipped is available at each of the Navy's principal industrial establishments, insuring facilities for the study of potential health hazards and for checking the effectiveness of existing control measures.

Other matters of paramount interest to the medical officer are: illumination, noise, fatigue, personal hygiene facilities, and the daily and weekly hours of work.

REPORTING OF OCCUPATIONAL DISABILITIES

It is obvious that adequate reporting and recording is required to keep industrial disabilities to the minimum and to serve as legal documents for the adjudication of compensation claims since the civil employee has both a moral and legal right to expect his government to maintain adequate permanent records to establish his right to compensation, and the tax payer has an equal right to permanent records to protect him against fraudulent claims for compensation against the government.

The Chief of the Bureau of Medicine and Surgery was directed by the Secre-

tary of the Navy to require a report of all accidents, injuries, and industrial illness occurring to Civil Service personnel employed by the Navy Department. This report covers both "lost-time" and "no-lost-time" injuries. In addition to sociological and medical data the basic reports serve to develop accident cause information. Close coördination and co-operation of the Medical Department with designated shop supervisors and safety officers is mandatory in order to attain accuracy of reporting. A responsibility of the shop supervisor is to furnish the accident cause information, thereby necessitating him to be familiar with the accidents occurring in his department. The original copy of each occupational disability report is mailed to the Bureau of Medicine and Surgery within, but not later than, 48 hours of the time of occurrence. In the Division of Preventive Medicine punch cards are cut from these reports and statistical analyses are prepared which serve as an index to control measures necessary.

From these analyses have come many advances in guarding machinery, protection against fumes from chemical processes necessary in the manufacture of munitions, control of the dust menace to health, etc.

CONCLUSION

The Navy's existing industrial hygiene program is paying dividends in decreasing lost time due to illness, decreasing the incidence of accidents, decreasing compensation payments, increasing production and efficiency, and promoting and maintaining morale of employees. It is recognized that there can be no relaxation of effort and to maintain efficient production there must be continuous active attention to prevent labor wastage.

Industrial Hygiene Activities in the Public Health Service*

JAMES G. TOWNSEND, M.D., F.A.P.H.A.

*In Charge, Division of Industrial Hygiene, National Institute of Health,
U. S. Public Health Service, Bethesda, Md.*

INDUSTRIAL health is a "prime contractor" in this nation's war. Today when every disabled war worker means less planes, ships, tanks, and guns, the national industrial hygiene program assumes an A-1 priority rating. The program which was put into effect 18 months before Pearl Harbor has felt increasingly the impact of war. Basic activities have progressed smoothly and with gathering momentum. Recent developments, however, deserve special mention since they demonstrate a closer integration of industrial hygiene with the war effort. There has been, too, a growing recognition of the "essentiality" of industrial health protection on the part of war agencies and civilian groups.

The current program of industrial hygiene in the Public Health Service follows the lines recommended by the Subcommittee on Industrial Health and Medicine of the Committee on Health and Medical Care in 1940, but has been greatly expanded during the war months. The program includes recruitment and training of industrial hygiene personnel, research, aid to state and local industrial hygiene services, special services for the War Department, and a promotion of coordinated health and

medical services for the industrial population.

During the past year the number of trained professional personnel employed in federal, state, and local services has increased to 500. There are now 38 state industrial hygiene organizations, 1 county unit, 3 city units, and 2 district units covering a large city and several adjoining counties. The majority of the personnel now employed in these units has been recruited and trained by the Public Health Service and detailed to duty in state and local industrial hygiene units.

The activities of the governmental industrial hygiene units have increased greatly during the past ten months. The expansion of the war industries since Pearl Harbor has been phenomenal. The number of workers engaged in war production had doubled in September, 1942, at which time 15 million were employed in war industries as compared to 7 million in December, 1941. It is estimated that, by 1943, the total will be 17½ million. For the past two years, the work of governmental industrial hygiene services has been directed almost exclusively to the improvement of conditions in industries engaged in the production of war materials. Hence, the wartime increase in workers to be served has severely taxed the staffs and facilities of the existing units. Preliminary analysis of reports to the Division of Industrial Hygiene

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

indicates that, in the fiscal year 1942, 32 state and local units reached some 5,000 establishments employing 2,400,000 workers.

In the immediate future and for the duration, the pressure upon the existing industrial hygiene facilities will obviously increase. The extent to which state and local units will be able to meet the demands depends very largely upon the ability of the Division of Industrial Hygiene to augment its funds and its program of recruitment, training, and assignment of professional personnel for war duty in these units.

Despite the fact that many staffs have been over-burdened, available industrial hygiene services have not yet been put to the maximum use. In many instances, serious problems have not been brought to the attention of state units. In other cases, units have not streamlined their procedure in order to speed up the correction of hazards in war industries. Time is the most "critical" material in total war. We should now give attention to ways of utilizing existing industrial hygiene services to the fullest degree and more efficiently. Certainly, there is ample opportunity to develop short-cuts in peacetime procedures, which will not lower essential standards of good industrial hygiene practice.

The Division of Industrial Hygiene also has been carrying on a coöperative program with the War Department for the protection of the health of workers in government-owned establishments. Approximately 150 have been certified to the division for thorough investigation. To accomplish this task, the division maintains mobile units, each consisting of 4 professional personnel, and the necessary supporting personnel at its laboratories. The mobile units have already completed surveys and made recommendations concerning the improvement of working conditions in 65 plants. Construction of many plants

is yet to be completed. If the Division of Industrial Hygiene is to speed further investigation and follow-up, it will be necessary to add more mobile units.

A committee to consider optimum hours of work has been formed by representatives of the Labor Department, the War and Navy Departments, the War Production Board, the Maritime Commission, the Department of Commerce, and the Public Health Service. After examining all available evidence, including studies made by experts and the practical experience of management and labor, the committee has made recommendations for the guidance of war contract plants as well as governmental establishments in establishing a schedule of hours of work best adapted to particular enterprises.

The Division of Industrial Hygiene is working with the Office of Civilian Defense to develop blackout procedures in factories and in effecting organization to deal with enemy attack on industrial centers.

A survey of the dispensaries and hygiene services in federal departments in Washington, D. C., was conducted by the division last spring. It was found that these dispensaries for the most part were established and administered by the departments and bureaus concerned, and that functions and activities varied widely. Of 85 dispensaries employing 155 nurses, not more than 20 were under the supervision of a physician. In no government agency was there found a comprehensive program of environmental and personal hygiene and preventive medicine such as is recommended for private industry. The over-all recommendations of the survey called for improvement in organization, personnel, utilization of space, and equipment in these dispensaries, with the provision that all should be operated under medical supervision. Since the completion of the survey, a number of fed-

eral agencies have adopted the recommendations and have sought the consultant assistance of the Public Health Service in the establishment of adequate industrial hygiene and medical services for federal employees.

In the field of research, much of the work of the Division of Industrial Hygiene is conducted for the Army and the Navy. The confidential nature of this work precludes reporting as to the specific projects and as to the results so far obtained. In general, however, these researches are concerned with numerous problems of aviation medicine and with the toxicology of explosives.

Investigation of occupational dermatoses has engaged much of the division's attention as a result of the use in war industries, of many new substances and processes. Intensive training of specialists in dermatology in occupational dermatoses was initiated during the past few months. A group of dermatologists from all parts of the country were invited to attend a brief training course at the National Institute of Health. These specialists have constituted themselves consultants on occupational dermatology in their communities, and their services are available upon request of industrial physicians in war industries.

Other new consultant services in the division have been established. Dr. S. J. Seeger, Chairman of the Council on Industrial Health of the American Medical Association, has been appointed consultant to the Division of Industrial Hygiene, for the purpose of securing closer coöperation between governmental industrial hygiene services and medical societies. A dental officer of the Public Health Service has been assigned to the division as dental consultant. He has been active in promoting the extension of dental services in industry through state and local health departments which already have dental hygiene programs. The objec-

tive is to include dental examinations in preëmployment and periodic health examinations; to coördinate the work of state dental directors and industrial hygiene directors; and to set up demonstration dental services in selected plants.

At the request of several important industries, ventilation studies are under way for the control of benzol and other toxic solvents now being substituted in many industries for toluene. Safe utilization of these potentially dangerous substances will be increasingly required as toluene becomes less and less available.

Progress has been made in collecting and compiling data on medical service facilities in plants representing all types of industry and three size classifications.

The Division of Industrial Hygiene has been active in stimulating the x-ray examination for tuberculosis of the workers in many war areas. In co-operation with the Office of Tuberculosis Control of the States Relations Division of the Public Health Service and the various state industrial hygiene divisions, a study of several types of x-ray technics for the diagnosis of tuberculosis and silicosis has been made. Mobile 35 mm. photofluorographic units are operating in several areas at the present time.

The medical history of World War I shows that mortality rates for tuberculosis increased greatly during the war years and for some years thereafter, especially in Europe. Today, the massing of armed forces for training purposes and the concentration of families and industrial workers in defense and cantonment areas, often under unhygienic conditions, becomes a hazard in controlling the spread of tuberculosis. Unless national efforts are directed toward combating specific factors in the tuberculosis problem, we may well expect an upward trend in the tuberculosis mortality curve for the

United States. Such an upward trend has already taken place in England.

The armed forces have already undertaken the examination of all enlisted men entering the Services. The next specific undertaking should be the examination of all industrial employees and an annual follow-up in certain groups.

The nation-wide survey of the duties of nurses in industry undertaken by the American Public Health Association in coöperation with the National Institute of Health has been completed. A preliminary report will be presented to this conference. The professions as well as administrators and health agencies will benefit greatly by the findings of the survey which has covered approximately one-third of the nation's industrial nursing force.

The Division of Industrial Hygiene has been active in the preparation and dissemination of information for professional personnel, for management and labor, and for individual workers. Reports of scientific investigations and statistical studies have been published and distributed widely. A monthly news letter reaches nearly 1,000 industrial hygienists.

In addition an outline of an industrial hygiene program in individual plants has been prepared and made available to labor-management committees of war production plants and other interested groups. This outline was prepared in skeleton form and mimeographed. It met with an unexpectedly large demand, some 5,000 copies have been distributed, and requests for several thousand more have come in.

A manual on engineering control of environmental hazards and a manual on medical service in industry have been prepared, both of which have been incorporated in the loose-leaf safety manual issued by the Plant Security Division of the Office of Ordnance, U. S. War Department.

A plan for preparation of a handbook for physicians on industrial hygiene has been approved by the Federal Security Administrator and the Surgeon General. The manual is being prepared by the professional staff of the Division of Industrial Hygiene under the editorship of Dr. Gafafer, and will discuss the outstanding problems of health conservation in the war industries.

Considerable progress has been made on an annotated bibliography on industrial psychiatry to be compiled under the joint sponsorship of the Health and Medical Committee, the National Research Council, and the National Institute of Health. It will be issued in a series of six or more bulletins. The title selected is "Mental and Emotional Hazards in Industry—A Field Bibliography for Industrial Psychiatry."

Two other publications are in production at present—the first an illustrated pamphlet interpreting to management, labor unions, and other interested groups the usual services of a state or local industrial hygiene unit, and the second an illustrated catalogue of industrial hygiene educational materials available from the Public Health Service.

To inform the professional groups further, throughout the country, governmental industrial hygiene services, state medical societies, and educational institutions have sponsored institutes for private physicians, nurses, and other professional groups. The Division of Industrial Hygiene has participated in many of these intensive training programs and will continue to do so.

I have briefly summarized activities now going forward in the combined effort of the civilian authorities for industrial health. Much still remains to be done. As I see it, the problem is not so much what to do but how to do it.

Since the development of industrial

health service is a relatively new field in public health, it is important that the objectives, functions, and achievements of industrial hygiene be interpreted to management, labor, and to the individual worker. The promotional program should be strengthened and extended to recruit the support not only of the professions, but also of the particular groups whom modern industrial hygiene would serve.

The problem of medical care for workers and their families is one of vital importance. Reports to the U. S. Public Health Service indicate that in many communities there are not available sufficient medical, dental, and nursing personnel, or hospital facilities, for the medical care of workers and their families. This problem arises not only from the rapid development of industries in the sparsely populated areas, but also from the shortage of professional personnel as the result of supplying the needs of the Army and Navy.

Nine in every 10 industrial absences because of disability are the result of diseases and accidents incurred off the job. A few progressive employers and unions have developed comprehensive medical services for workers and their families. On the whole, however, plant medical services and union health programs have not broadened their scope to include general medical care. In hard-pressed industrial communities, where no other facilities are available, industrial medical services should be extended to general medical care both for employees and their families. Since the shortage of physicians available for full-time industrial service impedes the expansion of in-plant programs, the practising physicians of war communities should be utilized to the utmost by industry. In fact, the industrial medical service, whether rendered by full-time professional personnel or not, should be closely coördinated with all

the public health, hospital, and medical facilities of the community.

If existing industrial medical services are strengthened and retained, approximately one-third of our workers will have available such services in their plants. The remaining two-thirds of our workers who are employed in small plants of less than 500 are at present virtually without needed industrial or medical health service. Appropriate action should be taken to meet these needs, and compulsion used if necessary to secure medical service in war contract plants. The British experience indicates that this can be done, given a proper assignment of medical personnel and a national policy.

The existing standards for employment of handicapped workers should be reviewed and adjusted to present needs. Among the several million handicapped persons in the United States there are many thousands who should be employed in war plants. The Division of Industrial Hygiene has joined with the U. S. Employment Service in a series of conferences to consider the employment of physically handicapped persons in the war industries. The policy recommended to the War Manpower Commission would require the employment of many thousands of persons with minor or major disabilities and would make the pre-employment physical examination an effective tool for the proper placement of all workers.

One of our major problems is that of community resources. Despite the expansion of public health services, many industrial communities are still providing meager public health, medical, and hospital services. The problem is especially acute in communities where large war plants have been constructed almost overnight and where tens of thousands of industrial workers have taken residence. Problems of over-

crowding, lack of sanitary facilities, and communicable disease control have arisen. The provision of adequate sanitary and public health services is primarily a local problem. Nevertheless, when local inertia retards the war effort, state and federal agencies have a clear responsibility to act.

It is an old public health maxim to strike hard where you can do the most good—that is, to center activities where the burdens of disability and premature death are heaviest and the opportunities for health conservation are greatest. Today, in this nation at war, the focal point is the industrial population—the men and women engaged directly or indirectly in producing or transporting the things we need to win.

For the past 25 years, study after study has been made and consistently demonstrated the fact that death and disability rates are higher among the industrial population than among any

other employed groups. During the same period, industrial hygiene, modern medicine, and the generalized public health program have proved beyond the shadow of a doubt that an astonishing proportion of this human waste can be prevented, at less cost than that of continued neglect.

At this critical time in our nation's history, it is imperative that all of us—individually and collectively—put that knowledge to the proof. The governmental industrial hygiene services—federal, state and local—are ready and willing to bring to bear upon the health problems of workers the full force of their preventive programs. It remains for them to redouble their efforts, both to extend the preventive program and to recruit the support of all available resources for adequate health care of America's workers upon whom—shoulder to shoulder with the armed forces—rests our fate and that of our children.

Unexpected Occupational Disease Exposures During Wartime*

JOHN J. PRENDERGAST, M.D.

Medical Director, Chrysler Corporation, Detroit, Mich.

THE subject assigned provides an opportunity to discuss what we think is the proper attitude of industry toward the health, safety, and comfort of its workers. In the Chrysler Corporation we hold firmly to the conviction that healthy workers are a valuable aid to production. We believe that the health of employees can and should be conserved, and that industrial health hazards can be anticipated and remedial measures prepared before practical exposure occurs.

Therefore, a complete industrial health program contemplates not only the treatment of disease but also the prevention of disease, and, since the prevention of disease requires the recognition of new hazards before they become operative, it may be open to question whether any occupational diseases should be unexpected. There are a number of materials which are new to industry and there are a larger number which have new applications. We presume that all of the elements have been discovered and a small amount is known about all of them. However, some of the rarer substances such as indium, gallium and osmium are now coming into wider use due to priority restrictions on older and more common materials. Also, some new organic com-

pounds are in use and possibly other new organic compounds will be introduced from time to time. By far the larger category consists of materials which have been known for a long time but which are now employed in new ways, although many old materials are new and unfamiliar to some industries.

GENERAL PAPER

In the following interesting cases which have come to our attention, it should be understood that we do not have the ideal solutions for every one of the problems found.

In the past, benzene has been restricted within the Chrysler Corporation so that we have had none of this material in our plants. Recently benzene was found in a new operation involving the polishing of reflectors where it was used as a flotation agent for the polishing material. Production people in charge, never having had any experience with benzene, were surprised to know that it was a toxic substance. A few trial runs indicated that a solvent naphtha, such as a hydrogenated naphtha, would take care of this problem satisfactorily. Because the hydrogenated naphthas are only slightly toxic, any possibility of major hazard is removed from this operation by its use. Since this problem has arisen, members of the Industrial Hygiene Division of the Medical Department have been able to make other suggestions which

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

materially improve the polishing properties of the compound used. This exemplifies the production gains which may be brought about through the investigation of hazardous materials.

Another compound which was not previously used by our Corporation, except for fire fighting fluids, is carbon tetrachloride. This material had been needed for a great number of purposes in the past but substitutes have been provided which are satisfactory in every way. Recently a survey of one of our gun plants indicated that a fairly large quantity of carbon tetrachloride was being employed on one operation. Investigation showed that a certain critical tapping and machining operation was using up to 25 per cent carbon tetrachloride along with a cutting compound in order to provide a technically satisfactory product within the very close tolerances demanded by the inspectors. Numerous cutting compounds had been tried and none had proved to be satisfactory. Tests on the operation showed that this condition was very unsatisfactory from the health standpoint in that serious illness might result among the workmen if corrections were not made. However, this work was so essential that, had a change been made in the operation, without a satisfactory substitute being provided, it is highly possible that the production operation would have ceased. Since this was undesirable, it was then suggested that small percentages of trichlorethylene might work satisfactorily from a technical standpoint. Test trials revealed that very small percentages of trichlorethylene would do as good a job as larger percentages of the more dangerous carbon tetrachloride. The operation is now using a maximum of 8 per cent trichlorethylene, and better production results are being obtained than when carbon tetrachloride in larger percentages was being used. The tests made with the interferometer

have shown concentrations which should cause no concern.

Certain other suggestions have been made relative to substitutes which will relieve all toxicity fears, should these substitutes prove to be technically good compounds. However, trichlorethylene is a satisfactory technical product and, since the toxic concentrations do not exceed 120 p.p.m., at any time and under any condition, it is doubtful whether further tests to introduce new substitutes will be useful. Trichlorethylene has shown some interesting properties in connection with cutting compounds and may prove to be valuable on other jobs.

The above mentioned materials certainly are not new and they probably would not be interesting except that the applications were not common and certainly were unusual to us. They are examples of old materials becoming important through new uses.

Lead tetraethyl, a compound which is used to increase the octane rating of motor fuel, is an example of a well known material which again is coming into more prominence due to the war requirements for higher octane aviation gasoline. Whereas in the past we had been accustomed to using a white gasoline with no lead in it and had received satisfactory performance because the octane rating of this white gasoline was sufficiently high to be technically satisfactory, we now find lead tetraethyl being used not only in the higher aviation grade gasoline but also in the lower grades of gasoline. This comes about because the various white gasolines are being "bumped up" to higher octane ratings. Thus the gasoline which you are buying at the corner gas station is now composed of a gasoline which has a much lower octane rating and additional amounts of lead tetraethyl. Indeed, some gasolines which previously have advertised their non-lead content now contain lead tetraethyl.

This becomes important because these gasolines are used throughout the plants for various washing purposes. Men get their hands, and sometimes other portions of their body, in it and lead absorption through the skin must receive our consideration. In this particular case, the correctional efforts involved an educational campaign among the workers and a change in our specifications. First, warning signs and placards were placed at all points where gasoline was dispensed for any purpose, which stated among other things that this leaded gasoline should not be used for any purpose other than for motor fuel. Suitable mineral spirit, mineral seal oil, or various grades of naphtha were then specified and used for all washing and cleaning purposes. In a few instances, other measures such as the installation of automatic degreasers or alkali washers were necessary.

A control problem is, however, introduced into those plants which are in multi-story buildings due to the fact that concentrations of lead higher than the maximum allowable may be introduced on elevators and in other inadequately ventilated closed spaces where jitney trucks and other motors may be running. These areas must be tested periodically. Other areas where high leaded gasolines are known to be used in tanks, airplane motors, and trucks must be studied to determine what additional control measures, such as increased ventilation, will be needed. Indeed, in some places, increased specific and general ventilation has already been provided.

Another example of an entirely new hazard is now mentioned. Several cases of dermatitis and conjunctivitis have been found in a new secret adhesive operation. It has been ascertained that the cement is the causative factor. However, due to the secret nature of the process and material, it is difficult to get accurate information on

all its components, and such information will have to be determined in the laboratory. Patch testing will be utilized to ascertain whether or not certain components in question are the source of the dermatitis and suggestions for possible substitutes will then be made. This may involve new organic materials or old ones which have not been previously studied. It is probable that substances which have not been fully investigated from the toxicity standpoint will be encountered in this particular instance.

It may be interesting to mention now a group of instances relating to dermatitis which have been of interest to us recently. In one case, a canvas tarpaulin material received from one company was used and no difficulty noted. However, the same material, with presumably the identical type of resin and dye impregnation, supplied by a different vendor, gave cause for complaint. Workmen got dye and resin into their skin and a very mild dermatitis resulted. In addition it was almost impossible for the employees to wash the dye from their hands and arms. Investigation revealed that the company supplying the material complained of indicated that the difficulty arose from the combination of the dye and the resin in the tarpaulin. Further, wartime needs caused the material to be shipped as soon as it was manufactured, with no proper period of time for aging. In addition, a new solvent was being used due to priority restrictions on the solvent which had previously been approved. In this case, inquiry directed to the company resulted in an admission that the above was true and that other similar inquiries had been received from a midwestern state health department. The material which was being received by our Corporation in a tacky wet state was immediately improved and new formula for the treatment of the canvas cloth was put into use by this company causing it to be entirely satisfactory.

Another situation in which a number of women were complaining of itching but of no severe dermatitis was found in a wiring department on airplane parts. Here the resin used in the wire coating did have some irritant properties though not enough irritation resulted to cause skin lesions. Chemical tests indicated the presence of cresol-like compounds. The skin might become slightly irritated but the main damage came from the scratching which resulted from the irritation. Because of this, the companies concerned in supplying this material were asked to deliver their products in a dryer and less tacky state. It was found that the resins which were used in the coating were not dried out sufficiently and the residual vapors were sufficient to cause irritation. Very definite relief was provided for the persons concerned by washing their bodies with sodium bicarbonate solution.

Another group of men working on bronze gun parts complained of an itching sensation and presented eczematous skin lesions. These lesions we have called "bronze itch" which is characteristically very much like what is listed in the literature as "copper itch." The condition predominated about the neck line, belt line, legs, ankles, and wrists, which indicated very definitely that it was a mechanical irritation. Patch and chemical tests were performed which bore out this conclusion. The remedy in this case consisted of personal cleanliness. A program of personal hygiene instituted immediately brought very great relief and this was supplemented by the introduction of a personal protective coating. Since these measures were taken, no further complaints have been received.

Another case analogous to this but having much more interesting possibilities was found in the airplane body work where aluminum chips and dust were getting into the men's clothes and over all parts of the body. The lesions

caused were apparently of two types but both were signified by the resultant pigmentation of the skin which lasted for a considerable period of time. It is possible that this pigmentation may result from the small percentage of magnesium which is found in this aluminum alloy. There is, however, the complication that this may be effected by irritants in the electrical wiring coatings mentioned before. In this instance, the maximum number of cases, as was the case with the "bronze itch," arose during warm weather. A program of personal hygiene immediately eliminated most of these cases but a few persisted which were characterized by an itching sensation and small hard papules which, on healing, were pigmented for a considerable period of time.

An entirely different kind of exposure has developed with the increase of horse power of airplane motors. While the testing of motors has always been a noisy operation, these operations had in the past been kept to a 90 decibel level or lower. However, the advent of engines of from 1,500 to 2,000 h. p. and upward has resulted in test rooms having noise levels of from 120 to a peak of 140 decibels even though scientific methods of sound-deadening rooms have been followed. In one instance, a test room having a noise level of 118 to 120 decibels had the control chamber, where all the operators are located, in a separate acoustically treated room, but even in this room the noise level was approximately 90 decibels. A suggested solution was the installation of sound-deadening baffles about the pipes and motor on a hinged arrangement so that ready access could be had to all parts of the equipment. Such devices can result in a lowering of the noise level from 12 to 20 decibels. Such reductions do not appear to be large but, when the very high level of sound is considered, this is a worth while reduction particularly when the nature of the scale used in deter-

mining the decibels is considered. A reduction of 2 decibels in these high ranges means the cutting of the volume of sound in half. Whereas a few years ago a noise level of 110 to 115 decibels was considered about the top, we are now faced with routine noise levels which are considerably higher. Somewhere around 125 decibels the problem becomes more involved than simply the loss of hearing. In fact, the hearing may be safeguarded through the use of personal protective devices but little is known concerning the vibrational effects on other parts of the human organisms at these higher levels of sound. All the men exposed to high levels of sound are now given special physical examinations which include, in addition to audiometer tests, complete clinical laboratory tests, basal metabolism, and electrocardiography. Close control maintained at frequent intervals on the individuals concerned should lead to the detection of injury before any becomes serious.

While the noise problem is not new, it was not fully anticipated that the noise levels would reach those mentioned above but, in view of the attempts to make louder and louder sounds for air raid sirens, it may be expected that still higher levels of sound will be found in special instances, and these higher levels presumably could cause some systemic damage unless guarded against. This, as far as we can see, will open an entirely new field of research in a field that is very old.

The mere increase in plant facility has introduced additional problems in all parts of the country. While new sanitation and housing loads have had recognition from the appropriate public health agencies, there have been problems introduced into the plants themselves.

Thus, when one new plant was built for government use by our Corporation, wells had to be drilled, the resultant water tested, and sanitary facilities provided. It so happened that the water

contained such large amounts of methane that, when a match was applied to a milk bottle full of freshly drawn water, the gases bubbling from the water would ignite and a blue flame would be maintained on top of the water for almost a minute. This gaseous content led to various explosive possibilities which were not wholly solved until a new source of water supply was brought into the plant. The appearance of this amount of gas also indicated the need for very thorough chemical and bacteriological examination of the water supply. In addition to the water supply, a small sewage treatment plant had to be provided. This plant, though modern in every respect, did give off some slight objectionable odors but this was not important as it was located a considerable distance from any plant activity. Recent plant expansions have brought the plant operations right to the doors of this sewage disposal unit, and some complaints have been made. This has resulted in the installation of a ventilation system over the exits to the sludge pits so that all odors were removed.

Probably the most unexpected occupational disease exposures have arisen as the result of the stringencies of the raw materials used in the war effort. In a War Production Board release of August 24, 1942, the following materials were listed in Class III as available in significant quantities as substitutes for scarcer materials: ferroboration, ferromanganese, gold, indium, lead, osmium, palladium, and sodium. When the large number of metals available are considered, this very small list, which includes a large proportion of formerly rare and expensive elements, is indeed unexpected. Of these elements and compounds, something is known concerning gold, lead, and sodium; a little less is known of ferroboration, ferromanganese and palladium; and very little is known concerning the acute and chronic toxic-

ties of indium and osmium. Some investigations have been instituted on indium within the Chrysler Medical Department. Reports will be made as phases of the investigation are completed. These substances and compounds mentioned above are important in view of the fact that these are the materials that the authorized agencies state are available for substitution. Already in-

dium is used in the surface treating of airplane engine bearings, and a considerable number of other uses are projected.

The determination of the hazards which might result from the use of these materials in numerous new applications assumes great importance in order that the health of the working population may be fully protected.

Impact of War on Children and Youth— Intensification of Emotional Problems*

MARTHA W. MACDONALD, M.D.

*Psychiatric Services Adviser, Children's Bureau, U. S. Department of Labor,
Washington, D. C.*

THE nations of the world that recognize and protect rights of the individual have been deeply concerned about the relationship between war and juvenile delinquency, not only since this war began but during and after the first world war. This concern is indicative of the present-day constructive attitude toward delinquency in children—namely, that the delinquent child is a sick child.

If I may extend this concept I would describe juvenile delinquency as a symptom of nutritional deficiency, a deficiency in the child's spiritual nutrition resulting in a stunting of ideals and a crippling of character, so that the child cannot administer his behavior to conform to the standards of the community.

Scientific observation suggests that the ability of a person to direct his behavior into satisfying and acceptable channels is dependent upon a complicated balance between gratification and renunciation.

Let us briefly view the mechanics of this. The child's first gratifications and restrictions are controlled by the parents, chiefly the mother at first. Later, the father, and then others in the family, school, and community become involved in this give and take of human relationship with the child. With growth come new and different gratifications and re-

quired renunciations, but none of these ever assume the basic importance of those that belong to the family. The child must in early months accept many restrictions and deprivations. He must be taught to accept conformity which requires renunciation of doing what he pleases, when, where, and to whom. He can accept this personal sacrifice and discipline only when he is assured of parental love in its place. He gradually accepts as his own the moral concepts that are taught him by the parent whom he loves. This is as it should be.

But why is the delinquent child different? In the majority of instances he is different because he has different feelings—he has not learned to love and admire anyone sufficiently to deny himself certain pleasures for the purpose of winning their love and approval. He sees himself as unloved and unaccepted by one or both parents. Any additional deprivation imposed by the limitations of family, community or state reinforce his feeling of unjust discrimination. Lacking an acceptable, strong, emotional tie which would form a basis for personification of ethical concepts, he develops a distorted conscience and weakened powers of resistance. All this makes him susceptible to any stimulating adventure within his reach that offers escape from the hurt of loss of love and pride. In return for security and adequacy within the family he attempts to settle for the security of the gang, the

* Presented at a session of the U. S. Children's Bureau, Commission on Children in Wartime, at the White House, Washington, D. C., February 4, 1943.

thrill of independence, and denial of dependence. His total behavior may be considered an expression of protest against keenly felt deprivation.

If we are to consider intelligently the problem of juvenile delinquency, whether in time of peace or war, we must examine the way in which the fundamental needs of all children are met, and must accept the importance of the fact that what needs are not met by the family unit must be met by the larger family—society. Let us see what happens to the child's fundamental needs in wartime.

Will he as an infant and small child get less mothering and less fathering in wartime with all that is involved in affectional relationship, physical care, personality development, and moral guidance? Will he be robbed of even the security of familiar surroundings because his family migrates? The small child robbed of the spiritual values of home is surrounded on all sides by the permissiveness of violence at an age when he needs so much mature help in controlling his own destructive drives. The young child is normally aggressive and destructive. Education in our culture is concerned with directing this drive into constructive channels. With war and his identification with warriors, the inhibition and sublimation of destructive drives becomes more difficult for him. The child will not receive the same assurance from the adult in wartime that killing and mass violence is wrong and that problems can be solved in other ways. For all these reasons young children need mothering more than ever before. They also need the presence of a father or father person, around whom to build their ideal of a good man.

School children need vastly more personal security and guidance. The school must feel greater responsibility for the child's life over and beyond the narrow limitations of a standard curriculum.

Curricula should be geared to modern living, with emphasis upon social studies and individual responsibility in community, state, and world affairs. Children today are seriously handicapped in their opportunity to believe in the inherent goodness of man and must be helped to understand the experiences that engender love and hate in all men. The church can contribute immeasurably to morale and character building for all children, providing the church, like other institutions, secures personnel of the stature for such responsibility. Ideals are molded by the patterns of personalities we admire. The child cannot build an ideal for himself unless he has the semblance of that pattern in the home, school, community, or church.

The adolescent with his approaching intellectual maturity but characteristic emotional instability reacts more noticeably to war than does the younger child. His basic personality and character potentialities are in a process of flux and are experiencing added physiological pressures. Most of his attitudes and behavior trends are well formed by now, but a testing out is required before final decisions are made and before a philosophy of life becomes more or less crystallized. War is contrary to all he has believed in or planned for. He does not have as yet the mature resignation to tolerate too much frustration, and war presents so many renunciations over and above the possibilities for gratification. Now at a time when he is struggling for mastery over his body and soul, he is bombarded with the haunting insistence to live—live fully and dangerously if necessary, for tomorrow may be too late. The physiological functioning of the adolescent demands activity. Inactivity bores him and creates internal tension which must find release. He is likely to resent the authority of any who would deny him freedom. The conflict between dependence upon the family and independence

normally reaches acute intensity at this period. With war challenging the productive abilities of all, most young adolescents are impatient to prove their personal worth. They want to work, whether in a war activity or at part-time work nonessential to the war. This is in part their protest against society considering them as children. The sudden assumption of mature responsibilities and privileges without the experience and training belonging to maturity can place young people in a social situation fraught with many dangers.

Yes, children of all ages will be subjected during the war to more of the experiences that make for delinquency than ever before. War intensifies many times the normal needs of all children. Does it not logically follow that whatever we do for the welfare of all children will be reflected in a lower incidence of delinquency? We trust that the majority of older children of today will be immune to the destructive influence and increased opportunities for delinquency growing out of war. But what of those children who are unstable—whose earlier experience has been lacking in character-building essentials? Just as the malnourished child has greater susceptibility to acute and chronic infections, so the neglected, unloved, and untaught child has less resistance to the forces that endanger character. This is the child who will become delinquent with the increased opportunity and who should receive special consideration. No community

can ever completely make up to these children for their early deprivations. Few communities will be able to do more than partially meet their accumulated and intensified needs. Facing the prognostic limitations growing out of the very nature of character formation and the nonavailability of skills for use in redirecting character trends, we should immediately focus our attention upon the safeguards and protection that the community can offer the youth who has not internalized the required restrictions in his own concept of behavior.

Protection needs to be particularly strengthened in the areas in which young people work and play. Experience should advise us that youthful discontents are selective in the activities they choose for expressing their unsatisfied hopes and desires. If we attempt to substitute one type of activity for another we should be guided by the interests and background of the particular group to be served.

The importance of leadership—dynamic leadership—acceptable to adventurous youth cannot be overstressed. Adolescent boys must have male leadership.

In conclusion, I want to express the belief that we are justified in our concern about juvenile delinquency. I say this not only in the interest of those boys and girls who will become delinquent during this war, but in behalf of all those who are now children and who will carry the responsibility of world peace and brotherhood into the future.

Trends in Laboratory Procedures in the Milk Control Program of St. Louis*

JANE HERSHEY, PH.D., HARRY WALDRIP, AND
JOSEPH C. WILLET, D.V.M., F.A.P.H.A.

St. Louis Health Division Laboratories, St. Louis, Mo.

ST. LOUIS, while operating under the standard milk ordinance, presents a special problem to the laboratory on account of two facts: the number of producers is relatively enormous (e.g., 20 times as many as those supplying San Francisco, of roughly the same population); and all milk marketed is pasteurized. The reasons for these facts are historical. The early city officials concentrated on moving the producers, as public nuisances, outside the city limits and then found themselves unable to claim any control over them. As the number of one and two cow producers among the neighboring farms and the size of the milkshed increased, pasteurization became an economic necessity to the city processing plants, especially in the hot season. While the number of shippers has declined in recent years, it is still over 4,000.

The peculiarities of the local situation have naturally colored the viewpoint of the laboratory. In addition to the routine problems, we are especially interested in discussing methods for examining large numbers of raw milks and for the phosphatase test.

The large number of producers is an excellent argument for the use of the simplest laboratory control procedures

authorized for individual shipper samples, but we are convinced that the methylene blue reductase test is the most valuable single test for such samples. Various workers have attempted to increase the refinement of this test by technical changes which increased its reproducibility (with regard to duplicating results on identical samples), but markedly altered the numerical values obtained.¹ Thornton² has pointed out that, without an absolute standard by which we can evaluate true accuracy, we should hesitate to sacrifice either the convenience or the significance, based on years of accumulated experience, of the old and simple version. Obviously, one sure way to increase the ability of the test to reflect fairly the quality of a given supply is to examine a larger number of samples from each source; and by working rather to simplify than to complicate technic, we can increase the number of samples that can be tested in a given period with a given laboratory staff. With this object we have adopted the following simplified procedure, which in no way changes the essentials of the present standard test³:

The samples arrive in the laboratory packed in ice water, and are left there until a large number, or the bulk of those expected, have come in; but we keep as far as possible within the statutory 2 hours. A pipetting machine, such as is used in serological labora-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 30, 1942.

tories, is filled with methylene blue solution after rinsing with chlorine solution, hot tap water, and sterile distilled water. The stoppers are removed from the tubes and the dye pipetted into the milk. The tubes, which are in racks holding 10, are stoppered with a strip of smooth-surfaced sponge rubber, long enough to cover the rack, held in a metal gripper. This is held so tightly against the mouths of the tubes that they may be inverted and shaken vigorously without leakage. As one rubber grid is used for shaking, an assistant rinses a second in running tap water and blots it with a fresh paper towel. The tubes are checked with their log and placed in a large water bath without further delay. The incubation and reading are conducted as usual.

In this fashion, two people can set up 1,500 or more tests in about an hour; the schedule works out so that the time spent in checking the tests into the bath is the same as the time taken for reading, so incubation periods can be exactly measured. The labor is virtually reduced to preparing the outfits for collection, taking the samples, and reading. The only deviations from the Standard Methods procedure³ are thus:

Use of pipetting machine—This is calibrated to deliver far more accurately than can the human worker under pressure. The cleaning process is so effectual that the dye as pipetted contains less than 1 bacterium per ml.

Leaving samples uncovered during incubation—Since they are kept in a covered water bath, air contamination is insignificant. Diffusion of oxygen into the milk is known to be too slow under these conditions for the absence of a stopper to have any effect on the reduction time. The rubber strip adds few or no organisms.

Mixing of the tubes at room temperature instead of at 37° C.—This permits the schedule to be maintained and,

since the tubes are warmed very shortly after mixing, should not affect the creaming.³

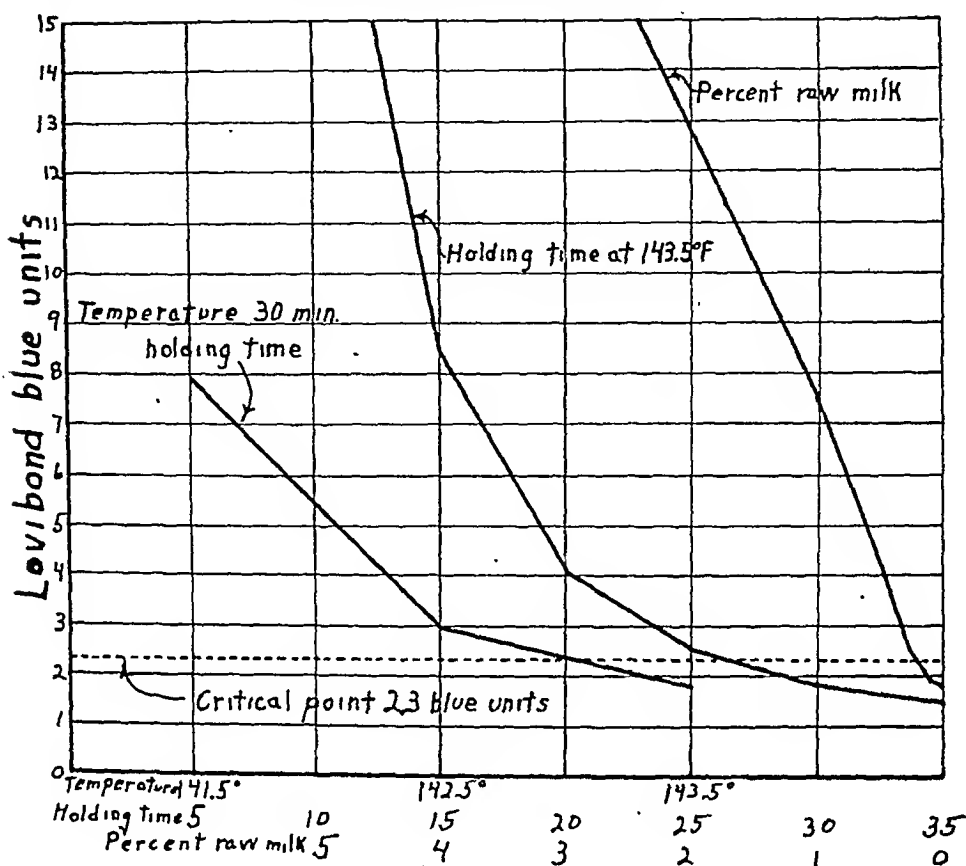

Some 40,000 samples are tested each year. Improvement in quality of the unprocessed milk is shown by the fact that only half as many samples are now reduced in less than 6 hours as in 1938.

As the methylene blue test has become our mainstay for testing raw milk, so has the phosphatase test for pasteurized milk. Extensive studies conducted here in 1937 showed that the Scharer⁴ field test (which did not then include solvent-extraction), with 1 hour incubation, and the original quantitative Kay-Graham,⁵ with 17 hour incubation, were equally sensitive in detecting experimental underpasteurization (as defined by local ordinance), or contamination with raw milk. After several months in which both were used, the short test was adopted as an exclusion test, and the Kay-Graham method retained only as a check on positive samples. Now all pasteurized products submitted for plate count are tested, the sample for the phosphatase test being pipetted immediately after that for the plate count, with the same pipette. Positive or suspicious samples are repeated in duplicate, with the prescribed controls, by the quantitative Kay-Graham method, and the results are reported in Lovibond blue units. The Milk Control Section, which receives the reports, has been supplied with a graph, based on the results of the experimental studies, on which blue units are plotted against holding time, temperature, and raw milk content (Figure 1). The section reports that it finds this graph very useful in tracing the source of violations.

In the last 5 years we have run 4,000 to 6,000 phosphatase tests a year. The percentage of positive reactions has dropped from 2.2 for milk and 4.3 for cream, to 0.3 and 0.8 respectively. Frankly raw milks are virtually not seen. It is obvious that even before the

FIGURE 1
PHOSPHATASE TEST

Correlation of underpasteurization and percentage raw milk in terms of Lovibond blue units using our modified test

introduction of the test, a remarkably good job of pasteurization was being done by the industry; now it is close to perfect.

Because of the requirements of the ordinance, we continue to make thousands of plate counts. We have only one or two comments on technic: we incubate plates only at 37° C., since 32° incubation in this climate would be expensive for the small dairy laboratories. We have modified the rules^{3,6} for counting plates to this extent: when our routine dilutions of 1:100 and 1:1,000 fail to produce plates within the 30-300 range, counts are reported literally as found, on the argument that below 30 the error is in the direction of making the count too high, and to report the

result merely as under 3,000 has the force of making it still higher; and conversely, when the 1:1,000 plate is over 300, the error tends to make the count appear lower than the actual, so less injustice is done by giving the found value than by reducing it to the blanket minimum of 300,000. As the counts are to be averaged with others, this seems the fairest procedure.

We have been subjected to an increasing demand for miscellaneous services beyond the strictly sanitary and nutritive control of milk; determinations of curd tension and efficiency of homogenization, diagnosis of mastitis, detection of plant contamination with thermophilic, thermoduric, and ropy-milk organisms, even surveys of local dairy

laboratories as to compliance with Standard Methods. Perhaps it should be pointed out that the laboratory service operates as an independent unit of the health division, not as a milk laboratory *per se*, and is able to exercise a certain amount of discretion as to function, attempting to stay rather strictly within the public health aspects of the job (we have for example decided that it is not our province to trace producers contributing thermophilic or thermotolerant organisms; and we test for mastitis only with reluctance). We are consequently interested in the policies of other health department laboratories and welcome this opportunity to acquire information, in the meantime relying for our clues on the emphasis in the manual of Standard Methods.

To summarize, our situation is this: the milk supply comes from frequently tested sources and is entirely pasteurized; there is an efficient inspection service, especially as to post-pasteurization processes; a virtually tamper-proof bottle closure is required; and in the phosphatase test we have an excellent laboratory check on pasteurization. We feel that where this situation exists, a shift in emphasis in laboratory control should be very seriously considered. It is probably generally agreed among

laboratory workers that bacterial counts (by whatever method) contribute little or nothing to controlling such a supply, and indeed at times actually detract from the control because of the logical absurdities encountered in the attempt to enforce bacterial standards. This is not to belittle the evolutionary or educational value of the procedure, but to emphasize its fundamental inappropriateness in the situation described. Rice⁷ has already voiced our obligation to reexamine critically such procedures with the object of eliminating what have become, with the passage of time, irrelevancies.

Prognosis in White and Colored Tuberculous Children According to Initial Chest X-ray Findings*

MIRIAM E. BRAILEY, M.D., DR.P.H.

Director, Bureau of Tuberculosis, City Health Department, Baltimore, Md.

THIS paper is concerned with the extent of chest lesion demonstrated at initial x-ray examination in a group of 1,148 tuberculous children whose infection was discovered prior to 15 years of age, and who have been followed for varying periods of time in a study of their mortality from tuberculosis. The data were taken from an outpatient clinic for tuberculous children conducted at the Johns Hopkins Hospital since 1928. This clinic admits tuberculin-positive infants under 2 years of age and keeps them under observation as long as possible. It also arranges for the examination of parents and older siblings in the appropriate public dispensaries of the same hospital, and thus maintains a family record which it attempts to keep up-to-date both for morbidity and mortality from tuberculosis. The records for analysis include those of infected children admitted to the special clinic during infancy, and also those of infected older siblings examined in the general pediatric dispensary. Infection was determined in the children of these families by their reaction to intradermal testing with old

tuberculin. All their x-rays have been reviewed by the author.

The races are somewhat unequally represented, there being 404 white and 744 colored children in the study. In both races about 60 per cent of the children whose records were analyzed were under 5 years of age at the time infection was discovered; something less than 30 per cent fell into the age group 5 to 9, and not much over 10 per cent fell into the age group 10 to 14. This concentration in the younger age groups is a reflection of the requirement that all the families followed must contain an infant under 2 years of age, eligible for care in the special clinic. There was no evidence of sex selection.

Roughly, one-fifth of the children of this study were brought to the dispensary because of some complaint, and tuberculous infection or disease came to light in the course of a complete examination which included the tuberculin test. The remaining four-fifths were examined only because of known tuberculosis in the family, usually an open case in an adult. Verification of household contact with open tuberculosis was somewhat less frequent for infected colored infants than for white children of the same age, and exposure from the community at large appeared to account for infection in a somewhat larger proportion of Negro infants. So far as *duration* of household contact could be estimated, colored children of this study

* From the Department of Epidemiology of the School of Hygiene and Public Health, The Johns Hopkins University, and the Department of Pediatrics of The Johns Hopkins Hospital, Baltimore, Md. The study was aided by grants from the Commonwealth Fund and the Maryland Tuberculosis Association. Read in part before the Epidemiology Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

had less exposure than white children; but this does not dispose of the possibility that colored children when in contact may have been more intensely exposed.

For both races the families studied belonged to economic groups unable to pay for medical care; and for the period of observation covered by this report the great majority were supported by public relief. Homes were overcrowded and far from ideal for both races; and while the average Negro families probably lived under even poorer conditions than the average white families, at this economic level the differences in environment were not striking.

The great majority of these children had only dispensary supervision during the most active phase of their tuberculous infection. This was especially true for children found infected before 6 years of age for whom the State of Maryland had made no routine provision in state sanatoria during the period covered by the study. A small number of white infants could be accommodated without expense at a private sanatorium; and both white and colored infants were occasionally admitted to

the pediatric services of general hospitals, though not infrequently when already ill with tuberculous meningitis or miliary tuberculosis.

DETERMINATION OF TUBERCULOUS INFECTION

All the children included in this analysis were considered to be infected with tuberculosis. The presence of infection was determined in most instances by the child's reaction to old tuberculin applied intradermally and read 48 to 72 hours later. A positive reaction was defined as one with at least a full centimeter of edema, erythema alone not being considered a definitely positive reaction.

Table 1 shows the various test doses of tuberculin and the number of children reacting to each dose at the time their initial x-ray was taken. It will be seen at once that there were 14 children either not tested or failing to return for readings, leaving 1,134 for whom a test and its result were recorded. Of these there were 7 for whom a negative reaction was noted, while the remaining 1,127 gave typically positive reactions.

Unfortunately, no consistent effort

TABLE 1

Number of Children Tested with Various Dosages of Old Tuberculin and Their Reaction at the Time of Initial Chest X-ray

<i>Reaction to Old Tuberculin</i>	<i>White</i>	<i>Colored</i>	<i>Total</i>
Positive to 0.01 mg.	36	101	137
Positive to 0.1 mg.	295	484	779
Total reacting to 0.1 mg. or less	331	585	916
Positive to 1.0 mg.	69	141	210
Positive to more than 1.0 mg.	...	1	1
Total reacting to 1.0 mg. or more	69	142	211
Total Positive Reactions	1,127
Negative to 0.1 mg. (Not tested further)	1	5	6
Negative to more than 1.0 mg.	...	1	1
Total Negative Reactions	1	6	7
No tuberculin reading recorded	3	11	14
Total Children Tested	1,134

was made to discover the smallest test dose of tuberculin necessary to produce a positive reaction; and accordingly this study can throw no light on the relationship between allergy level and extent of lesion. In 916, or 80.8 per cent, of the 1,134 tested, a reaction was obtained with 0.1 mg. or less of tuberculin; in 210, or 18.5 per cent, 1.0 mg. of tuberculin was used as a test dose when infection was discovered. Not infrequently 1.0 mg. was employed unnecessarily when the interval had been rather long since the latest negative result with that dosage.

Table 1 indicates a colored child reacting positively to a dose larger than 1.0 mg. of tuberculin. The test dose in this case was 2.0 mg., and it was applied to a year old infant with a chronic cough who was repeatedly negative to smaller doses. This child had five older siblings all of whom had become definitely positive to 0.1 mg. of tuberculin during association with fatal tuberculosis in the father, whose death took place before the infant in question was born. Later this patient coughed up half a peanut, his rather dubious x-ray findings cleared completely, and allergy could never be demonstrated at ordinary levels. In the light of observations such as those made by Furcelow, *et al.*,¹ who observed a high proportion of pseudo-reactions even among children requiring 1.0 mg. tests, it is possible that this child was never truly infected with tuberculosis. This is the only instance in the study where the author thinks infection is somewhat doubtful.

There are 6 children shown in Table 1 who gave negative reactions to 0.1 mg. and were not tested further. One was a white child of 11 years of age whose initial film showed a typically calcified primary complex. Of the 5 colored children in this category, 2 were less than 1 year and 2 years old, respectively, and both were suffering with acute miliary tuberculosis when brought to the dis-

pensary. Death occurred within a few days. Three others whose ages in two instances were 8 years and in the third 10 years, all showed well calcified nodes at the hilum in their initial chest films.

The colored child classified in Table 1 as negative to doses of tuberculin larger than 1.0 mg. is of special interest. She was 2½ years old when an extensive pneumonia of the left lung was discovered which showed no change in appearance and no indication of resolution during a hospital admission lasting nearly 5 months. During this interval repeated tuberculin testing was done, and the dosage increased to 10.0 mg. with only negative response. Repeated efforts to recover acidfast bacilli from the sputum and gastric contents failed. There had been known contact with sputum-positive tuberculosis in an adult member of her family for several weeks prior to the discovery of her lung condition. Another bout of exposure took place between her discharge at 2 years and 11 months, and her readmission at 3 years and 3 months, for pertussis and supposed pertussis pneumonia. On the second admission it became quite clear that a generalized tuberculosis was present, and this was proved at autopsy one month later. During the last month of her life small doses of tuberculin had been applied but not increased beyond 0.1 mg. and she was so acutely ill that her failure to react was not surprising. At autopsy a bilateral and very extensive tuberculous involvement of the tracheobronchial lymph nodes was found and blocks of tissue from the chronic pneumonia of the left lung revealed tuberculosis. It seems likely that from the age of 2½ years she had suffered from pulmonary tuberculosis, in spite of lack of allergy, and therefore she is included in this study from that age.

In addition to the children just described whose tuberculosis was considered to be established in the absence of a positive tuberculin reaction, there were

14 others included in Table 1 for whom no tuberculin test was recorded. Three were white children giving a history of contact with tuberculosis and ranging in age from 9 to 12 years. All 3 displayed calcification at the lung root, typical of old mediastinal tuberculosis. There were 11 untested colored children. Four of these were examined because of contact and showed calcification at the mediastinum; their ages were from 7 years to 12 years. The remaining 7 colored children all presented evidence of manifest tuberculosis on their first visit and all of them proved to be fatal cases: one, a boy of 14 years of age, was ill with advanced reinfection tuberculosis and lived only 3 days; the others were instances of fatal primary disease: a child of 6 years who lived nearly a year, and 5 others, all of them under 3 years of age and surviving from a few days to several months.

The foregoing discussion is an attempt to show that in the 21 instances where children have been included in this analysis without a positive tuberculin, the initial x-ray evidence of calcification of tracheobronchial lymph nodes, or of extensive pulmonary disease leading to an early death from tuberculosis, has been considered adequate evidence that the child was tuberculous at first observation.

INITIAL X-RAY FINDINGS IN TUBERCULOUS CHILDREN ACCORDING TO AGE AT DISCOVERY OF INFECTION

In making an analysis of initial x-ray findings it was essential to use only broad classifications. There were films without definite lesion in spite of the known positive reaction to tuberculin; a second group contained those showing only nodal lesions at the mediastinum, with or without the characteristically small primary focus visible; and a third class was made for the parenchymal lesions of the childhood type, nearly always rather gross shadows resembling

pneumonias and invariably associated with enlarged mediastinal nodes. Instances of miliary dissemination were entered in this class as well. A separate grouping was made for reinfection tuberculosis with its typical soft infiltration, usually beginning peripherally and nearly always located in the upper lobe, and in most instances appearing long after the primary complex had healed. When the same film showed lesions quite different in type, it was classified as belonging in the group considered to contain the more serious and extensive disease.

Tables 2 and 3 show the initial x-ray findings for white and colored by separate years to age 5, then for age groups 0-4, 5-9, and 10-14. Inspection of Table 2 for 404 white children shows that infected infants under 1 year of age had the smallest percentage of negative films and the largest percentage of parenchymal lesions of any age up to age 15. Only about 33 per cent escaped lesion of some kind, 22 per cent showed nodal tuberculosis, and 45.5 per cent displayed parenchymal involvement of the childhood type. As age increased, parenchymal involvement at first x-ray examination became less common, and had fallen to about 18 per cent for children age 1 year, and was found in only 8 per cent of the children examined for the first time at age 2 years. After 5 years of age, involvement of the lung parenchyma occurred only twice in 168 infected white children. One of these cases was reinfection tuberculosis in a 6 year old child whose disease became arrested after several years of observation. By 5 years of age it was usual to encounter nodal lesions of the mediastinum in about 30 per cent of the children examined for the first time, and this remained fairly constant to 15 years of age.

The corresponding tabulation for 744 colored children is shown in Table 3. Percentages for the first year of life are

Total	744	366	49.2	196	26.3	177	23.8	5	0.7

almost identical with those for white infants. Colored tuberculin-positive children, however, continued to show this high prevalence of parenchymal involvement not only under 1 year, but also at age 1 and at age 2, with percentages at ages 3 and 4 years beginning to drop off and to approximate the findings for white infants at age 1 year. In colored children infected before 5 years of age, parenchymal lesions were found at first x-ray in nearly 36 per cent of those examined, while for infected white children of similar age, such extensive involvement was encountered in 19 per cent.

For infected colored children more than 5 years of age when first examined, there was a marked drop in the prevalence of serious lesions, but they were

much more numerous than in the white children of the same age. Parenchymal disease of the childhood type never dropped lower than 5 per cent at any age.

While there were only 5 cases of reinfection tuberculosis discovered at initial examination among 744 infected colored children, it should be said parenthetically that 19 others developed this type under observation; while in the white children studied, the one child among 404 who showed it on admission was the only instance encountered at any time in white children of this series.

MORTALITY FROM TUBERCULOSIS

In studying mortality from tuberculosis in these children, the number of

TABLE 4

Mortality from Tuberculosis During Various Time Periods After Discovery of Infection in 178 White and 334 Colored Children Found to be Tuberculin-Positive Before 3 Years of Age

Interval from discovery of infection	Number of deaths during interval		Mortality per cent during interval	
	White	Colored	White	Colored
First year	8	37	4.5	11.2
First 5 years	14	57	8.1	18.3
First 10 years	14	59	8.1	19.8

observed deaths was related to the duration of observation of each individual, making it possible to calculate the risk of dying within 1 year or for any longer interval of time after the discovery of infection. The procedure followed was the modified life-table method, the application of which has already been described in detail in earlier publications.^{2, 3}

Mortality tables were set up for 10 years of observation of children falling into two different age groups at the time infection was discovered: those infected before age 3, and those found to be infected between ages 3 and 15 years. Only summary tables are presented here, derived from the more detailed calculations of the probability of dying.

Table 4 presents in summary form the mortality from tuberculosis in 512 children infected before age 3, of whom

178 were white and 334 were colored. For both races deaths were more frequent during the first year following discovery of infection than for any later annual period, and they account for more than half the mortality observed over ten years. At every time period shown, the colored suffered a mortality more than twice that of the white. For the first year following the discovery of infection, mortality was 4.5 per cent for the white and 11 per cent for the colored; at the end of 5 years the cumulative mortality for white was 8 per cent and for colored was 18 per cent. For the whole 10 year period, mortality from tuberculosis stood at 8 per cent for the white and had risen to 20 per cent for the colored.

In Table 5 the 512 children infected before 3 years of age are classified according to the presence or absence of

TABLE 5

Mortality from Tuberculosis in 512 Children, Infected Before Age 3, During Various Time Periods Following the Discovery of Infection, According to Lesion Shown at Initial X-ray Examination

		Deaths from Tuberculosis					
Race	Number of Cases	Within 1 year		Within 5 years		Within 10 years	
		Number	Per cent	Number	Per cent	Number	Per cent
Parenchymal lesion in first x-ray							
White	43	7	16.3	9	20.9	9	20.9
Colored	140	31	22.1	44	32.4	46	35.8
Total	183	38	20.8	53	29.6	55	32.0
No Parenchymal lesion in first x-ray							
White	135	1	0.8	5	3.9	5	3.9
Colored	194	6	3.2	13	7.6	13	7.6
Total	329	7	2.2	18	6.0	18	6.0

parenchymal lesion in initial x-ray, and their mortality studied with these differences in mind. One hundred eighty-three showed parenchymal involvement, only one of which had reinfection tuberculosis. There were 329 children who showed only nodal disease or films without definite lesion.

Among 183 children showing parenchymal disease, 38 deaths from tuberculosis occurred within 1 year, a mortality of 21 per cent. This had risen to 30 per cent by the end of 5 years, and to 32 per cent by the close of 10 years of observation. Although mortality for the 43 white children during the first year of observation was 16 per cent while that for the 140 colored children was 22 per cent, this difference was not large enough to exclude the operation of chance. At later time intervals this racial difference became greater, the 10 year mortality being 21 per cent for white and 36 per cent for colored.

The remaining 329 children infected before age 3 whose first films showed no parenchymal lesion are shown in Table 5, with a combined mortality for the first year of observation of 2.2 per cent, to be contrasted with the first-year mortality of 21 per cent for children showing parenchymal shadows. By the end of 5 years of observation, the cumulative mortality for the combined races had become 6 per cent with no increase in mortality thereafter; and this figure is roughly one-fifth the risk noted for children admitted with more extensive disease.

The two races showed a difference in the force of mortality where the initial film showed no parenchymal lesion. The first-year rate for white children was 0.8 per cent; for colored it was 3.2 per cent, a fourfold difference. At the end of 5 years the rate had risen to nearly 4 per cent for white and 7.6 per cent for colored, and these rates stood for the total 10 year risk of death from tuberculosis.

The 140 colored children with initial parenchymal involvement, shown in Table 5, represent 42 per cent of the infected children examined under 3 years of age, while the 43 white children admitted with definite pulmonary lesions represent only 24 per cent of the infected white children under 3 years of age. This difference is highly significant statistically. The higher mortality from tuberculosis in colored children appears to be associated with their tendency to develop extensive lesions of the lung parenchyma more frequently than do white children. It has been shown in an earlier publication that even if they are admitted without parenchymal disease, they show a greater tendency to develop it within the next few months than do white children of similar age.⁴

Mortality became greatly diminished for children found to be infected later than age 3; and separate analyses for various age groups, each containing only small numbers of children, failed to reveal striking differences in the risk of death. Accordingly, children admitted at any age between 3 and 15 years of age have been considered together, and the mortality for 226 white and 410 colored children at various time intervals following infection is shown in Table 6 in summary form.

Only one death took place among the 226 white children. This occurred in a child admitted to observation with tuberculous pneumonia at age 6 and dying of tuberculous meningitis a few weeks later. This mortality of 0.4 per cent represents the total 10 year risk and is in contrast to the 10 year mortality of 8 per cent for white children infected prior to 3 years of age.

In the group of 410 colored children, 12 deaths from tuberculosis took place during the first year of observation, giving an observed mortality of 3 per cent. This rate had risen to 5 per cent by the end of 5 years, and to 7.6 per cent at the close of 10 years, a figure

TABLE 6

Mortality from Tuberculosis in 226 White and 410 Colored Children Whose Infection Was Discovered Between Age 3 and Age 15 Years; no Separation for Lesion

Interval from discovery of infection	Number of deaths during interval		Mortality per cent during interval	
	White	Colored	White	Colored
First year	1	12	0.4	3.0
First 5 years	1	20	0.4	5.3
First 10 years	1	25	0.4	7.6

to be compared with a death rate of 19.8 per cent calculated for colored children infected before 3 years of age. The colored have a mortality only about half as high if they are found to be infected later than age 3. It is interesting to see how closely the mortality rates for the older *colored* group approximate those for the younger *white* group. Thus tuberculin-positive colored children at their more favorable period in childhood have a mortality from tuberculosis which just about equals the rates of infected white children at their more critical period.

The study of mortality in older children of the white race, according to extent of initial lesion, proved to be very simple. The 222 white children found infected after age 3 and showing no parenchymal involvement initially were all alive at the time these records were compiled. There were only 4 instances of initial parenchymal involvement and of these 1 had died within 1 year.

As usual, however, the colored presented a more striking picture. Forty-two of the 410 colored were admitted with pulmonary lesions visible in the initial film, and this 10 per cent is to be contrasted with 42 per cent showing such lesions when infection had occurred before 3 years of age. Thirty-seven of these 42 were regarded as parenchymal lesions of the childhood type, and their mortality can be compared with that of younger colored children showing comparable lesions.

Table 7 shows the mortality of these older colored children according to the presence or absence of childhood parenchymal lesions. There were 37 with parenchymal lesion and 368 without this finding initially.

Among the 37 instances of initial parenchymal disease, 9 deaths were observed during the first year of clinic observation, giving a mortality of 24 per cent; this had risen to nearly 34 per cent by the end of 5 years, and to 38 per cent for the whole 10 years of

TABLE 7

Mortality from Tuberculosis in 405 Colored Children Whose Infection Was Discovered Between Ages 3 and 15 Years, According to Initial X-ray Findings*

Initial x-ray findings	Number of cases	Deaths from Tuberculosis					
		Within 1 year		Within 5 years		Within 10 years	
		Number	Per cent	Number	Per cent	Number	Per cent
Parenchymal lesion	37*	9	24.3	12	33.7	13	38.2
No parenchymal lesion	368	0	4	1.3	6	3.3

* Exclusive of 5 cases of reinfection tuberculosis, 4 of whom died.

follow-up. These rates are nearly identical with those for colored children shown in Table 5 whose initial examination before age 3 years showed parenchymal involvement. It is probably justifiable to conclude that, for the colored, parenchymal lesions of the childhood type at any age during childhood carry about the same risk of death that they do in infancy.

The 368 colored children between the ages of 3 and 15 years, when examined and found to have no parenchymal lesion, showed similar percentages of nodal lesions and negative films as the younger group; yet this older and larger group suffered no deaths at all during the first year of observation, had a mortality of only 1.3 per cent by the end of 5 years, and a total mortality from tuberculosis of 3.3 per cent by the end of 10 years. This 10 year rate was less than half that calculated for colored children with comparable lesions whose infection took place before 3 years of age. We conclude that as the colored child grows older, if his tuberculous infection has produced no more than nodal disease at the time his infection is discovered, he has more capacity to control his disease than the infant with nodal involvement.

In Table 7 it was noted that there were 5 children of the colored race whose initial films showed reinfection tuberculosis. Their ages were 4, 6, 9, 13, and 14 years respectively. Four of these died in less than 2 years, 1 of

tuberculous meningitis rather soon after the discovery of tuberculosis, the other 3 of pulmonary tuberculosis. The 5th child, a girl of 13 years of age when observation began, had been followed 6 years when these records were compiled, and at that time her disease was considered arrested. Reference has already been made to 19 colored children admitted without reinfection tuberculosis who developed this type while under observation. There was only one white child of this study who showed reinfection tuberculosis on admission, and none was observed to develop it subsequently.

There was a total of 73 deaths from tuberculosis in children whose infection took place before 3 years of age. Fourteen of these fatalities were among white, and 59 among colored children. The immediate cause of death is shown in Table 8. Extra-pulmonary tuberculosis, notably miliary tuberculosis and tuberculous meningitis, accounted for more than 80 per cent of these deaths, and tuberculous pneumonia appeared to be the immediate cause of death in 16 per cent. Reinfection tuberculosis accounted for only 1 per cent. In the same table are shown the 24 deaths occurring in children whose infection was discovered between ages 3 and 15. All but one of these fatal cases were colored. Extrapulmonary tuberculosis was the immediate cause of death in less than 42 per cent, tuberculous pneumonia was considered responsible for death in 17 per cent, and reinfection

TABLE 8

Immediate Cause of Death from Tuberculosis in 73 Children Infected Before Age 3 and in 24 Children whose Infection Was Discovered Between Ages 3 and 15 Years

Cause of Death	Infected before Age 3 Years		Infection Found Between Ages 3 and 15 Years	
	No. of deaths	Per cent	No. of deaths	Per cent
Miliary Tuberculosis	32	43.8	4	16.7
Tuberculous Meningitis	26	35.6	6	25.0
Other Extrapulmonary Tuberculosis	2	2.7	0
Post-Primary Tuberculous Pneumonia	12	16.5	4	16.7
Reinfection Tuberculosis	1	1.4	10	41.6
Total Fatalities	73	100.0	24	100.0

tuberculosis was the cause of death in the remaining 42 per cent.

SUMMARY

In a series of 404 white and 744 colored children less than 15 years of age when found positive to tuberculin, chest lesions demonstrable at initial x-ray examination were more frequent and more serious in extent the younger the child. Infected children under 1 year of age behaved with remarkable similarity irrespective of race, showing enlarged tracheobronchial lymph nodes in about 22 per cent and extensive lesions of the lung parenchyma in 47 per cent. For *white* children a prompt reduction in the frequency of parenchymal lesions was noted as early as age 1 year, but *colored* children showed a sustained high prevalence of such lesions at initial examination for the first 3 years of life and barely approximated the decreasing risk noted in 1 year old white infants by the time they had reached 5 years of age.

Among older children, between 5 and 15 years of age at first examination, roughly 30 per cent of infected children of both races showed nodal involvement. For the *white*, parenchymal lesions of any kind were rare, occurring in less than 2 per cent. For the colored, parenchymal involvement of the childhood type appeared in nearly 6 per cent of initial films, and lesions of reinfection tuberculosis were seen in more than 1 per cent at first examination.

Over a 10 year period of observation, mortality from tuberculosis in white children infected before age 3, was calculated to be 8 per cent, while for colored children it was nearly 20 per cent. For both races more than half the risk of death was concentrated within the first year of known infection. Where infection was discovered between ages 3 and 15 years, the 10 year mortality

for white children was 0.4 per cent, and for colored it was 7.6 per cent.

Mortality was much higher for children admitted with parenchymal lesion. For the combined races, if infection took place before age 3, mortality was 21 per cent within 1 year, had risen to 30 per cent by the end of 5 years, and to 32 per cent for the whole 10 year period. Evidence was presented suggesting that white and colored suffer about equal risk of death if parenchymal disease can be demonstrated. The colored show many more of these serious lesions than do white children. Lesions of the lung parenchyma on first x-ray in older children of the colored race carried the same mortality as in younger children, but at these ages they were less frequent.

The total 10 year mortality from tuberculosis in white children infected before age 3 and showing only nodal lesions or negative films was about 4 per cent, while for the colored it was 7.6 per cent. White children presenting similar findings at first x-ray between ages 3 and 15 suffered no mortality during the period of observation, but colored children between these ages whose initial films showed no parenchymal lesion suffered a mortality of 3.3 per cent within a 10 year observation period. The lower death rate in children past infancy appears to be related to the lessened frequency of parenchymal involvement and to an improved resistance to nodal lesions.

Public Health Organization in Mexico*

MARIO QUINONES, M.D.

Secretary General, Federal Department of Health, Mexico City, Mexico

SINCE the present Constitution of Mexico was enacted in 1917 public health in Mexico has been under the care of an autonomous institution, which is a part of the executive branch of the Federal Government. It is the Federal Department of Public Health and the National Council of Health. Its chief is a member of the Presidential Cabinet.

This was the first step taken on becoming aware of the great vital public health problems which the nation has to solve. As health education of the public spread over the country and new demands for health activities came from every corner of the nation, there followed a progressive increase in the budgets to meet the ever increasing requirements for health. On the other hand, the rapid development of communications has opened the road to the propagation of infectious and parasitic diseases which before were restricted to certain zones, with the result that the ancient division between national and local problems has been broken down. Thus, although the supreme sanitary law, the Federal Sanitary Code, marks the division of activities for federal and local authorities, it also invests the Federal Department of Health with full authority to act when the health of the nation is in danger, or when there is a neglect of duty by a local government. The last federal Sanitary Code was en-

acted in 1934, and by it the Federal Department of Health is authorized, first, to nominate a representative for every state and territory, and, second, to sign agreements with the local governments to coöperate with them and coördinate their efforts to get a single direction and orientation in the solving of public health problems either of general or local interest. This coöperative plan permits the Department of Health to guide and supervise all health activities over the country, and avoids many misunderstandings and duplication of activities which existed when several health organizations operated in a single state.

In effect then the basic organization of public health in Mexico is centralized in the state health officer, who is appointed by mutual agreement of the federal and local governments, and under this arrangement. With steadily growing appropriations, it has been possible to enlarge services, increase their number, and improve the health of the people at large.

The appropriations of the Federal Department of Health during the present decade are shown in Table 1.

TABLE 1

Year	Appropriation	Per cent of Federal Budget
1933	\$6,532,487.46	2.79
1934	7,499,945.81	2.91
1935	10,480,000.00	3.80
1936	12,940,000.00	4.50
1937	14,870,000.00	4.46
1938	13,900,000.00	3.33
1939	16,500,000.00	3.70
1940	16,500,000.00	3.69
1941	19,000,000.00	3.88
1942	24,000,000.00	4.35

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

To these appropriations must be added appropriations of the individual states, so an average of \$1.00 to \$1.50 Mexican currency has been spent per capita during the last five years.

The advantages of the newer arrangement can better be understood on matters of sanitation and control of communicable diseases, as the Federal Government is more able to provide for economical and technical resources than is a local one. Further, when such problems arise, the Federal Department of Health is free to mobilize its forces in a kind of guerilla warfare, without hurting the sovereignty of an individual state.

In accordance with these general purposes, the Federal Department of Health is organized to extend its activities to all the aspects of modern public health practice. The present basic organization is as follows:

A. National Board of Health—

The National Board of Health, created by the Constitution of 1917, has advisory legislative, and judicial powers. It is formed by the heads of the higher offices and the directors of technical and administrative offices. They hold sessions every week and more often when an emergency arises.

B. Federal Department of Health—

1. Higher offices

a. Chief of the Department

As stated above, the Chief of the Department of Health in Mexico is a member of the Presidential Cabinet. He orients the general policies and guides the activities of the Institution.

b. Secretary General

The Secretary General has a rank equivalent to an undersecretary, and his activities are executive. He is in charge

of all the technical activities of public health.

Depending directly upon the Secretary General are:

- (1) *The School of Public Health and Hygiene*
- (2) *The Office of Technical Supervision*
- (3) *The Office of International Interchange*

c. Chief Clerk

The chief clerk or higher officer handles all matters concerning the administrative and financial aspects of public health. Under his care are the general administration office, the offices of administrative inspection, and legal administrative procedures. In the latter respect, it is worth while to state that the Federal Department of Health acts in a judicial capacity, as it can fine or even imprison any offender without any legal warrant, provided such an action is based on the law and regulations. This authority is extended to health officers in the states.

The different activities in public health are under the care and direction of the following group of divisions, which act in an advisory and supervisory capacity.

Such divisions can be gathered under three main headings:

A. Technical—

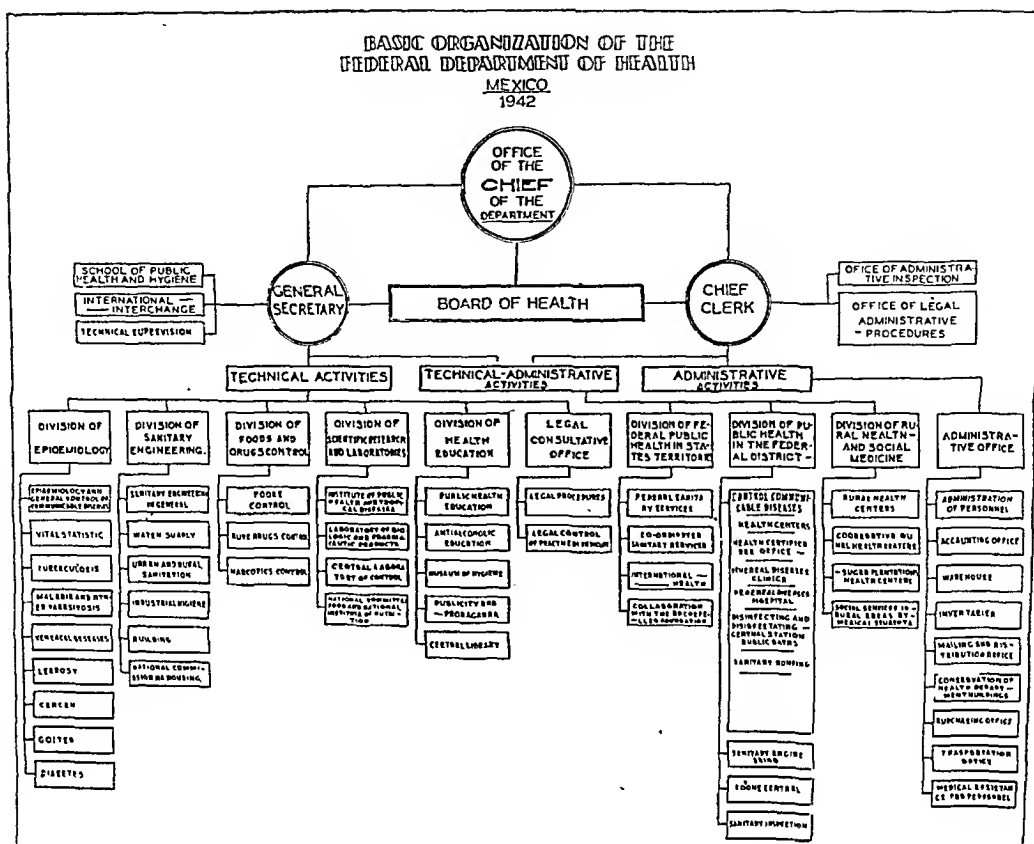

1. Division of Epidemiology

- a. Bureau of Biostatistics*
- b. Bureau of Epidemiology and General Control of Communicable Diseases*
- c. Bureau of Tuberculosis*

With this Bureau, the National Tuberculosis Committee coöperates very efficiently, and coördinates its efforts against tuberculosis.

d. Bureau of Malaria and other Parasitosis

Malaria and other parasitic diseases

like hookworm and onchocerciasis constitute such a problem in Mexico that the Federal Department of Health has established a special bureau in order to give particular attention to the solution of these vital problems of rural communities.

e. *Bureau of Venereal Disease Control*

f. *Section of other Preventable Diseases*

Several sections are in charge of the prophylaxis of leprosy, cancer, goiter, diabetes, and other preventable diseases.

2. *Division of Sanitary Engineering*

The Division of Sanitary Engineering includes various bureaus in charge of general sanitary engineering problems, urban and rural sanitation, industrial hygiene, the housing commission and water supplies. This last activity is one of the most important of this division.

It may seem paradoxical that, although Mexico is a tropical country, it is at the same time a dry one, and the Federal Government has to provide many rural zones with public water supplies. A special fund is set aside to finance water for rural communities.

3. *Division of Pure Foods and Drugs*

4. *Division of Research and Laboratories*

a. *The Institute of Public Health and Tropical Diseases for Research Work*

b. *The Central Laboratory*

c. *The Laboratory of Biologicals and Pharmaceuticals*

d. *The National Nutrition Committee and Institute*

5. *Division of Health Education*

The Division of Health Education orients and directs all educational activities to the public and provides the means and materials for such purposes.

A Museum of Hygiene in the City of Mexico was inaugurated during this year and it is growing progressively.

6. *Law Consulting Office*

This office is in charge of all matters concerning legal procedures and legislation. It also controls the practice of medicine and its branches.

B. *Technical and Administrative—Public Health Practice—*

1. *Division of Public Health for States and Federal Territories*

This division is the central office for all the state health organizations, and has control over all of them. Through a special bureau all matters related to quarantine services are supervised and controlled. A special bureau organized with the Rockefeller Foundation, the Office of Specialized Health Services, experiments with new methods of health practice, particularly in rural zones.

2. *Division of Rural Hygiene and Social Medicine*

Due to certain characteristics of rural Mexico, which constitutes about 80 per cent of the country, and due more particularly to our rural organization and distribution of land, the Federal Department of Health has been obliged to organize institutions which provide for medical care and public health activities in those rural zones which belong to rural communities and coöperative systems, called "Los Ejidos" (The Commons).

The health and medical care of people in these organizations are taken care of by the rural health centers which are financed either by the Federal Government alone, by coöperation with the "Ejidatarios" (commoners), or by the farmers themselves. This undoubtedly represents a step forward in the solution of the numerous problems with which Mexico has been faced since our Inde-

pendence days. It is augmented by co-operation with the Faculty of Medicine. This division sends to the field under its care and auspices, students of medicine who have finished their studies and are required to work during 6 months in the field before getting their diplomas. This plan serves three purposes, i.e., to provide rural communities with medical services they never had before, to find out through the surveys made by those students the problems of the zones in which they work, and to give the student a practical idea of the problems they will have to face in their future practice.

C. *Administration and Finances—*

To this end, the Department of Health concentrates all its administrative and financial activities in a central office which is under the jurisdiction of the chief clerk as stated above.

SUMMARY

In summary, this rapid glance at what Mexico is doing to solve its tremendous health problems and to keep step with the rest of the civilized world, emphasizes once and again that in public health administration there are neither standards nor norms which can be applied to every country, to all zones, and to all places alike. But at the same time we are aware that public health administration must be dynamic and never static.

So Mexico is looking forward to higher and higher standards of medical and health work, and to a more complete utilization of the invaluable aid which medicine, both curative and preventive, can give to its people, when it is practised in a coöperative spirit; but watchfulness and unselfish pains are always necessary, whatever the particular lines enlarged application of medical efficiency may take, and as the poet said:

Does the road wind uphill all the way?
Yes, to the very end, my friend.

Health Education in a War Relocation Project*

EDNA A. GERKEN, F.A.P.H.A.

Supervisor of Health Education, U. S. Indian Service, Denver, Colo.

I HAVE been asked to tell something of my recent two months' experience in a War Relocation Project. What of the organization for public health education among people torn from their homes by the necessities of war? I can give you a picture of the problem. I can point out some of its difficulties and some of its possibilities. I cannot, as yet, describe the problem as solved nor the program for health education organized. Public health workers, however, may recognize some of the factors present in this situation as characteristic of other new communities which are springing up throughout the land.

Migrations within civil populations have been unprecedented since Pearl Harbor. The evacuation of all citizens as well as aliens of Japanese ancestry from the west coast is only one example. While the military removal of civil populations is a strange experience in America, the shifting of populations through other necessities is not new. The "dust bowl" of the Middle West caused one such migration. The present increase of armed forces with the concomitant mushrooming of industry has brought another.

Americans and aliens of Japanese ancestry living on the west coast have

gone through a cataclysmic period since February 19, 1942, when the Secretary of War was given authority to prescribe military areas from which "any or all persons may be excluded." As a war-time necessity the War Department has evacuated some 100,000 persons from the west coast which was designated a military zone. Never in American history has there been a similar forced migration of such gigantic proportions.

These people, well over 60 per cent of whom were American born citizens, educated in public schools, taught by Caucasian teachers, schooled in democratic living, abandoned their homes and business enterprises and went to temporary assembly centers to await the preparation of permanent relocation projects. Dangerous aliens or individuals whose loyalty was suspected were not included here but were interned in prison camps. Relocation projects for these people have now been set up in 7 different states and are 10 in number. They were designed to provide habitation for evacuees and to give them an opportunity to work at industries which contribute to the country's present need, namely, food production and the manufacture of certain war materials.

Near the western boundary of Arizona on the Colorado River Indian Reservation 90,000 acres of fertile mesquite covered land lay waiting development into irrigated farms early in April. A dam had recently been completed so that water might be taken from the

* Presented at a Joint Session of the American School Health Association, and the Public Health Education and Public Health Nursing Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

river. Otherwise it was untouched desert. On May 12, just one month later, the first of the evacuees began to arrive. By the first week in September the population had risen to 17,819, and the settlement under the name of Poston had become the third largest city in the State of Arizona.

During this short period Army engineers had superintended the construction of barracks, the installation of a water system, the building of a sewage disposal plant, the construction of food storage facilities in a climate where temperatures reach well over 120°, and the building and equipment of hospital and clinic facilities for a community of 20,000 people.

The camp is laid out in 71 blocks, each of which houses some 250 or more people in 14 barracks containing 56 separate rooms, each 20 feet wide and 25 feet long. Separate buildings provide shower and toilet facilities for men and women, and there is a laundry building. Each block has one mess hall and kitchen and a recreation building for meetings and other activities. The necessities of life were thus provided in a wilderness for 20,000 people accustomed to 20th century American standards of living. Men, women, and children faced a new life and new work. How did they go about it?

The first step when a block was filled with evacuees was to organize a temporary local administrative staff. A block manager was chosen from the group. His function was to look after the needs of his community, listen to requests and complaints, pass on information for the guidance of the people, and to provide the channel for interchange of information between the general administrative staff of the project and the people.

The first duty of the manager was to see that the people were fed. Volunteer cooks were solicited from the group. The preparation and serving of food in the common mess hall would have taxed

the ingenuity of experienced and well trained cooks. The divergent tastes of youth, American born and accustomed to American food habits, and the tastes of old age, still clinging to the culture of the mother country, had to be met. Infants, who in addition to special milk formulae, required simple well cooked foods suitable for the first year of life, must be fed. The runabout child with his growth and energy requirements, not yet ready to digest and assimilate the highly seasoned combinations of food which older people crave, must be looked after. There were diabetics and minor cases of illness whose special feeding the home could not now provide. All of these nutritional problems were faced by volunteer cooks with no training and certainly no extensive understanding of the health implications involved.

The matter of nutrition gave the administrative staff deep concern. Careful checking, which showed that some of the 71 mess halls provided excellent food from the same supplies that seemed inadequate in other kitchens, indicated the problem to be one of local leadership. Plans were initiated for training each kitchen staff in the preparation and serving of palatable food, the planning of adequate menus from the food available, and for giving special training to selected persons in the preparation of food for infants and children and for invalids.

Rationing and transportation difficulties were two factors which entered into the problem of nutrition. These will increasingly disturb nutrition everywhere. Knowledge of food values and of alternate sources of essential foods is necessary to meet these problems.

Before discussing the organization of the community for health education it is necessary to understand the needs of the people and some of the peculiarities of the community in which they live. Some of the factors observed at Poston are common to other migrant groups,

and as such may possess significance to public health workers in areas given over, for example, to war industries.

A cursory investigation revealed at once the tremendous need for education, not alone for information, or for training in procedures for health protection, but over and above all else, for assurance, for morale, for a sense of security, for mental hygiene, by a people whose lives had been wrested from their foundations.

Here were people, many of whom had come from urban communities, suddenly thrust out on the desert, deprived of the security of their own homes, their accustomed community organization and services, and their economic independence, facing unknown, and to them terrifying, dangers. The heat, the dust, the rattlesnakes, the scorpions and the spiders were all factors in an environment new and strange and threatening. Regardless of the seriousness of these threats, the people needed to be reassured. They needed to know how to live in safety and some degree of comfort in temperatures above any they had ever experienced. They needed to know how to use salt to replace that lost by the body through perspiration. They needed to know, as the dust swirled around them in clouds, that dust blown from an open field, disagreeable as it may be, is a nuisance rather than a health hazard and that it does not threaten them with tuberculosis or silicosis. They needed to know the truth about the danger from insects and to have their fears removed regarding rattlesnakes.

Fear of the unknown is instinctive and is necessary to self preservation in an unfriendly world. But freedom from fear is one of the freedoms Americans are fighting for and it requires education. To enjoy security, health, peace of mind, man must know and understand the environment in which he lives.

Here was a community in which adequate provision had been made for the

necessities of community living; for safeguarding health through proper facilities for sewage disposal; through a safe and well guarded water supply; through an organized and well equipped fire department; through food doubly inspected and safeguarded as to quality and safety. Here was a community provided with a hospital staffed by well trained physicians and surgeons and equipped to meet any ordinary emergency. Yet, with all this, fears based on ignorance of what had been done to safeguard the community were rampant. Rumors that the water was not safe, that the sewage disposal plant was inadequate, that the fire fighting equipment was not up to standard, that the food was spoiled, that the hospital could not perform the simplest emergency operation ran through the community to destroy morale. The community needed to know the services that had been provided and how to use them wisely.

The situation at Poston was not unusual. Any community, be it old or new, must provide opportunities for the public to become familiar with community services if these are to be satisfactorily used. The best community services in the world fall short of fulfilling their function when the people are not secure in their use.

Large numbers of calls came in to the hospital for medical home visits—calls in excess of what could be met by the limited medical staff. In some cases these were for urgent conditions, but more often they were for minor ills. There was need for educating the public in the proper use of the medical facilities. With the increasing shortage of medical services available in every civilian community it is increasingly important that this education be provided everywhere.

The changed pattern of living, from that of the home unit to a group of fifty or sixty families, sharing a community mess hall, community showers

and latrines and laundry, presented another problem. It is difficult enough for soldiers to give up the privacy of home life and to share responsibility for the sanitation of a community shower and latrine, and to accept food which has been prepared to meet the needs of the group rather than the tastes of the individual. It is doubly hard for this adjustment to be made by whole families. Here again were unnecessary fears, bred by ignorance.

There was the fear of "athlete's foot," without adequate knowledge of how to protect oneself; fear of contracting one of the social diseases through the least likely avenue of infection, the common shower and latrine; fear of undernourishment because it was impossible to provide food for the family in the usual way. Mothers in particular needed help in making the adjustment to a new way of caring for their families. Their feeling of frustration in giving up control of the family life was acute. Yet there were constructive things to be done for the family that were within their control. Training in infant care and in home care of the sick were never more needed.

Turning from the problems felt by the people to a consideration of the group itself, an important characteristic is discovered. A new community lacks at first the coherence that makes work with it as a group possible. Coming from different localities, from all walks of life, and from divergent backgrounds, no one at first knows his neighbors and their capacities, or their potential contribution to the life of the community. People have not yet bound themselves together. Farm women living side by side with university graduates found little community interest. How helpful cohesiveness within a group can be is more fully appreciated after one has attempted to work in a community in which it is lacking. At Poston it was observed that some communities got to-

gether more quickly than did others and that those offered better opportunities for educational programs. The members of such groups came from similar backgrounds.

Another characteristic in this community was the fact that the channels through which education can function most effectively were not yet available. The health educator who goes into a new community will find it necessary to work with other groups on organization and the development of channels through which information may flow and by means of which members of the community may undertake to solve their own problems.

Under the leadership of the administrative staff, community services for the entire camp were organized. A census of the entire population was taken, and information as to the specific abilities of each person was classified. An employment bureau utilized this information in locating qualified individuals as they were needed for various tasks. A recreation department to provide immediate activities for young and old during the difficult period of adjustment was set up.

Church groups were organized. Daily vacation Bible and Buddhist schools were opened. Parents asked for nursery schools and young women volunteers organized these very creditably. Plans began to take shape for public schools, and young men and women, college graduates untrained in pedagogy, volunteered to take special teacher training which the administration offered. Volunteers set about making building bricks of adobe, since no materials were available for constructing schools. A news sheet was started by a group of young reporters and journalists. Adult classes in English and women's clubs began to appear. The machinery of self government was set up under the leadership of the legal members of the administrative staff and young evacuee lawyers.

Thus the channels for education began to take shape. The health department was organized under two branches, hospital and clinic services on the one hand, and public health services on the other. Under public health were included activities for communicable disease control, for sanitary inspections, for maternal and child welfare, for community nursing, for vital statistics and records, for nutrition, for health education.

If new communities lack the usual established channels for educational work, there are advantages to counterbalance this handicap. No set pattern can hamper the development of the program in accordance with the best thought of the present moment. It is possible to take the reports of national professional organizations, defining, for example, the functions of a health educator, and use these to set up the pattern for health education activities in the health department. The outline for school health policies, approved by recognized national groups, can be used to direct the program planning of the public school system. The lack of previously conceived ideas which might block sound development of the program is a decided advantage.

Because the slate was clear at Poston, plans could be made to permit maximum participation of the community in the discussion of its own problems. The organization of a Board of Health, on which were to be placed lay representatives of the community in addition to representatives of the professional group, was proposed. A channel would thus be provided through which the community could be kept in-

formed as to the thinking that went on behind the passage of health and sanitary regulations. This channel would also serve to keep professional workers informed as to special situations in the home and community that had a bearing on the acceptance of these regulations. In this way the health program would stem from the community itself under the guidance of professionally trained personnel.

The health educator, working under the health department, utilizing the various channels opening up throughout the community, interpreting the community and its services to the people, will be able to bring about better understanding and better use of the services provided, and to bring new security to the people.

The need and opportunity for health education in this war relocation camp are doubtless a duplication of needs and opportunities in innumerable other communities throughout the land. The break-up of old patterns of living; the insecurity of masses of people living in new surroundings; the urgency of the need in industrial and civil and army life for man power, unhampered by physical ailments and mental stresses; the steadily diminishing professional health services in civil life, must all be faced. Whether in an evacuee camp or in factory or training center where essential war industry is going forward, a clear-cut recognition of the problems existing in communities made up of migrant groups is needed. The development of sound educational programs is one part of our program for winning the war.

Field Observations of Tuberculosis Patients in Rural Areas of Tennessee*

R. S. GASS, M.D., ANN DILLON, AND W. C. WILLIAMS, M.D., F.A.P.H.A.

Tennessee Department of Public Health, Nashville, Tenn.

THE Tennessee Department of Public Health has maintained for a number of years mobile field units for tuberculosis case finding in the rural sections of the state. A clinician and an x-ray technician, using portable x-ray equipment, conduct regularly scheduled clinics in counties with local health departments.† Organization of the clinics and subsequent follow-up service are the responsibility of the local health officers and nurses. Recommendations concerning reexamination, collapse therapy, and frequency of nursing visits are sent to the local health officer and the private physician with the report of the x-ray findings for each person examined. Since hospital facilities are limited for residents of the rural sections of the state and treatment must be carried out at home, the personnel of the local health departments have considerable responsibility in the control of the disease.

In order to understand fully the tuberculosis problem, information is necessary concerning the progress of the cases subsequent to diagnosis. What happens to the persons diagnosed as having tuberculosis? How long do they live? What effect does the extent of the lesion and sputum status have on mortality? What percentage receive hospital care? Answers to these and similar questions

are valuable in formulating effective measures for the control of this disease.

Through regular visits to tuberculosis patients the local nurses routinely gather information which can be used in answering these questions. The local health departments are asked to send in periodically certain data which are readily available from records in the office. Query sheets are sent from the central office each month, requesting information concerning the present status (living or dead) of each case, whether or not collapse therapy has been received during the past twelve months, and dates of hospitalization for treatment of tuberculosis during that period.

These query sheets were first used in 1937 to learn the status of the cases diagnosed in 1936. The same information was requested concerning persons with active lesions and with lesions considered arrested at the time of diagnosis and, also, of children with first infection type lesions that were causing signs and/or symptoms. This paper presents the experience of tuberculosis patients diagnosed in field clinics from 1936 to 1940, inclusive. Nearly all of the data published elsewhere regarding the subsequent course of tuberculosis patients relate to persons who have received institutional care, while this study is concerned with patients of whom only a small percentage received hospital care or any form of special treatment.

In all, 5,056 white and 599 colored persons were under observation for periods of time varying from a few

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

† The field units do not conduct clinics in the four counties with cities of 100,000 population or over since those counties have their own programs.

TABLE 1

Classification of Cases of Tuberculosis According to Activity and Extent of Lesion on Diagnosis, by Color and Sex

Activity and Extent of Lesion	White			Colored		
	Total	Male	Female	Total	Male	Female
Total Cases	5,056	1,989	3,067	599	258	341
Active						
Minimal	1,057	345	712	159	57	102
Moderately Advanced	1,151	478	673	141	59	82
Far Advanced	946	423	523	216	110	106
Arrested						
Minimal	1,497	557	940	60	22	38
Moderately Advanced	320	148	172	7	3	4
Far Advanced	9	5	4
Manifest First Infection	76	33	43	16	7	9

months to five years. The classification of these cases, according to activity and extent of lesion, by sex, is shown in Table 1.

Of the white cases regarded as active, 1,057 were classed as minimal, 1,151 as moderately advanced, and 946 as far advanced. The largest group of white patients (1,497) was that with minimal arrested disease, while the largest colored group (216) was that with far advanced disease. There were 159 colored persons with minimal active lesions, 141 with moderately advanced active,

and only 67 with lesions considered arrested when first diagnosed. A higher proportion of the white patients under observation were females than males. This was due to a preponderance of females among those with minimal lesions, both active and arrested. Among the colored patients, also, the proportion of females was greater than that of males.

Since the age distribution of the cases is important in studying mortality, data are presented in Table 2 for three age groups, by color.

TABLE 2

Age Distribution of Cases of Tuberculosis According to Activity and Extent of Lesion on Diagnosis, by Color

Activity and Extent of Lesion	Total		Under 35 Years		35-54 Years		55 Years and Over	
	Number	Per cent	Number	Per cent	Number	Per cent	Number	Per cent
White								
Total Cases	5,056	99.9	2,231	44.1	1,938	38.3	887	17.5
Active								
Minimal	1,057	100.0	692	65.5	297	28.1	68	6.4
Moderately Advanced	1,151	99.9	517	44.9	424	36.8	210	18.2
Far Advanced	946	100.1	556	58.8	272	28.8	118	12.5
Arrested								
Minimal	1,497	99.9	349	23.3	788	52.6	360	24.0
Moderately Advanced	320	99.9	35	10.9	155	48.4	130	40.6
Far Advanced	9	100.0	6	66.7	2	22.2	1	11.1
Manifest First Infection	76	100.0	76	100.0
Colored								
Total Cases	599	100.0	414	69.1	143	23.9	42	7.0
Active								
Minimal	159	100.1	113	71.1	37	23.3	9	5.7
Moderately Advanced	141	100.0	92	65.2	40	28.4	9	6.4
Far Advanced	216	100.1	174	80.6	30	13.9	12	5.6
Arrested								
Minimal	60	100.0	18	30.0	32	53.3	10	16.7
Moderately Advanced	7	100.0	1	14.3	4	57.1	2	28.6
Manifest First Infection	16	100.0	16	100.0

For the most part, those under observation were young adults with a higher percentage of colored patients in the younger age groups than of white. Of the individuals with active tuberculosis, 73 per cent of the colored and 56 per cent of the white were under 35 years of age. Persons with arrested lesions at the time of diagnosis were older than those with active lesions.

MORTALITY EXPERIENCE

One method of studying mortality is to compare the actual number of deaths from all causes with the number expected. The actual number of deaths and the expected number,* according to activity and extent of lesion, with the ratios of actual to expected deaths, by color, are shown in Table 3.

colored patients with active tuberculosis were: 3.6 to 1 for those with minimal lesions, 13.6 to 1 for those moderately advanced, and 64.2 to 1 for those with far advanced disease.

The 71 deaths observed in the white group with arrested lesions when first diagnosed were only slightly more than the number expected, 62.4, and the numbers of actual and expected deaths were the same for the colored patients with arrested lesions. Consequently, the death rate is not materially increased by persons with such a diagnosis.

When the data were divided according to age at death, the ratio of actual to expected deaths was higher in the age group under 35 years than in the older age groups for persons with active tuberculosis. However, there was no

TABLE 3

Actual and Expected Deaths Among Tuberculosis Cases, with Ratios, According to Activity and Extent of Lesion on Diagnosis, by Color

Activity and Extent of Lesion	White			Colored		
	Actual Deaths	Expected Deaths	Ratio Act./Exp.	Actual Deaths	Expected Deaths	Ratio Act./Exp.
Total Cases	909	116.4	7.8	233	13.8	16.9
Active						
Minimal	49	16.8	2.9	16	4.5	3.6
Moderately Advanced	220	25.4	8.7	45	3.3	13.6
Far Advanced	567	11.3	50.2	167	2.6	64.2
Arrested	71	62.4	1.1	3	3.2	0.9
Manifest First Infection	2	0.5	4.0	2	0.2	10.0

In this group of cases over 1,000 (909 white and 233 colored) deaths from all causes occurred, with more than one-half among those with far advanced disease. Only 49 deaths occurred among white patients with minimal active disease and 16.8 were expected in that group. In the moderately advanced active group, 220 deaths occurred, or 8.7 times as many as were expected, while among the far advanced there were 50 times as many as expected. The ratios of actual to expected deaths among the

difference in the ratios according to age for those with arrested lesions. In considering these data from the viewpoint of administration of a tuberculosis program, it seemed advisable to discontinue follow-up service to individuals with arrested disease when diagnosed, since the mortality of this group was of the same order as that in the general population.

The experience in the state for white persons with active tuberculosis has been compared with that in Williamson County, Tenn.,^{1*} and with that in Cat-

* To determine the number of deaths that would be expected, the age-specific death rates from all causes in Tennessee for the years 1938-1939 were applied to the population in each group.

* Data presented here for Williamson County include those contained in previous publications and also data gathered subsequent to publication.

taraugus County, N. Y.,² as shown in Table 4. Those diagnosed as tuberculous in the field clinics include persons examined because of symptoms referable to the chest and contacts of known cases. In Williamson County, the experience includes all known cases of tuberculosis in the county. The Cattaraugus County data are similar to those of Williamson County in that the method of selection of patients was the same. One difference between the two studies is that a high percentage of patients in Cattaraugus County received hospital care.

The ratios of actual to expected deaths were smaller for the Williamson County cases than for those diagnosed in field clinics in the state. This is probably due to the fact that the Williamson County data include individuals with little or no disability, as well as a larger proportion of cases in the older age groups. For Cattaraugus County,

TABLE 4

Ratio of Actual to Expected Deaths Among Active White Cases of Tuberculosis by Extent of Lesion on Diagnosis, for Rural Areas of Tennessee, for Williamson County, Tenn., and for Cattaraugus County, N. Y.

Extent of Lesion	Rural Tennessee	Williamson County	Cattaraugus County
Minimal	2.9	0.7	5.3
Moderately Advanced	8.7	4.2	9.9
Far Advanced	50.2	13.9	48.1

however, the ratios were of the same order as those obtained for the rural areas of Tennessee.

In order to determine how long these patients live after diagnosis, the cumulative mortality from all causes during the first five years after diagnosis has been computed according to the method outlined in a previous publication.³ Table 5 and Figure 1 show these percentages for the patients with active tuberculosis, by extent of lesion and color.

FIG. 1

CUMULATIVE MORTALITY FROM ALL CAUSES, PER 100, AMONG ACTIVE CASES OF TUBERCULOSIS DURING FIVE YEARS FOLLOWING DIAGNOSIS, BY EXTENT OF LESION AND COLOR

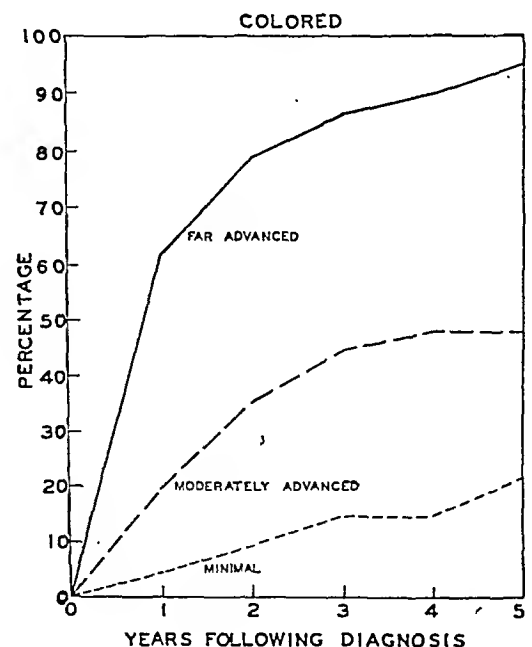

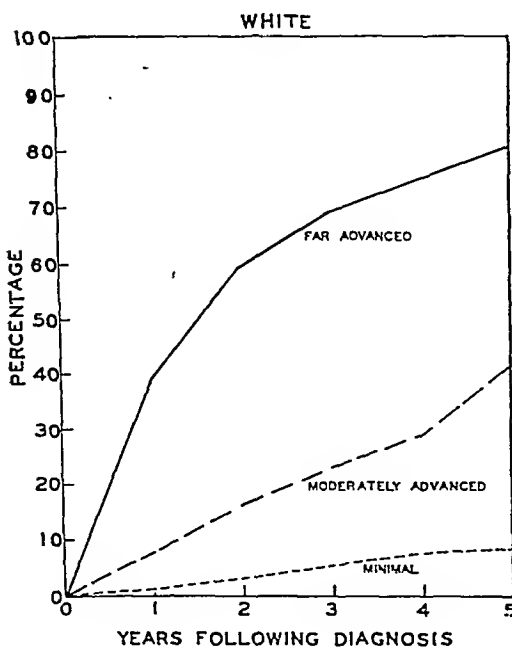

TABLE 5

Cumulative Mortality from All Causes, per 100, Among Active Cases of Tuberculosis During Five Years Following Diagnosis, by Extent of Lesion and Color

Years Following Diagnosis	Minimal		Moderately Advanced		Far Advanced	
	White	Colored	White	Colored	White	Colored
1st	1.3	4.5	8.1	19.5	39.2	61.6
2nd	3.4	9.6	16.5	35.1	59.6	79.1
3rd	5.7	14.8	23.7	44.6	69.5	86.7
4th	8.0	14.8	29.3	48.2	75.5	90.3
5th	8.7	21.6	42.0	48.2	81.1	95.2

Mortality was excessive during the first year after diagnosis for persons with far advanced lesions, since 39.2 per cent of the white and 61.6 per cent of the colored cases were dead by the end of the first year. By the end of the fifth year, 81.1 per cent of the white patients having far advanced disease and 95.2 per cent of the colored had died. In the moderately advanced group, the mortality was much lower. Of the white patients, 8.1 per cent died during the first year and 42.0 per cent were dead by the end of the fifth year following diagnosis. The percentages were higher for the colored, 19.5 the first year and 48.2 by the end of the fifth. The mortality experience of white patients with minimal lesions was low. Only 1.3 per cent of these died the first year after diagnosis and only 8.7 per cent were dead by the end of the fifth year. For the colored, the percentages were 4.5 the first year and 21.6 by the end of the fifth.

To study mortality according to sputum status, the active white cases were classified according to results of sputum

examinations made within two months of the date of diagnosis. Since the sputum was positive in only 7 of the minimal cases within that period, subsequent mortality could not be studied. Of the moderately advanced group, 176 had positive sputum and 218 negative sputum at the time of diagnosis. Of the far advanced group, the numbers were 389 and 50, respectively. Table 6 and Figure 2 show the cumulative mortality of the active white cases with moderately advanced and far advanced lesions according to sputum within two months of diagnosis.

The cumulative mortality in moderately advanced cases with positive sputum was much higher than that observed in those with negative sputum. The percentage dead by the end of the first year was 13.7 for those with positive sputum and 7.1 for those with negative sputum. By the end of the fifth year, over half (58.3 per cent) of those with positive sputum had died and slightly less than a fourth (24.3 per cent) of those with negative sputum. Among the patients with far advanced lesions and

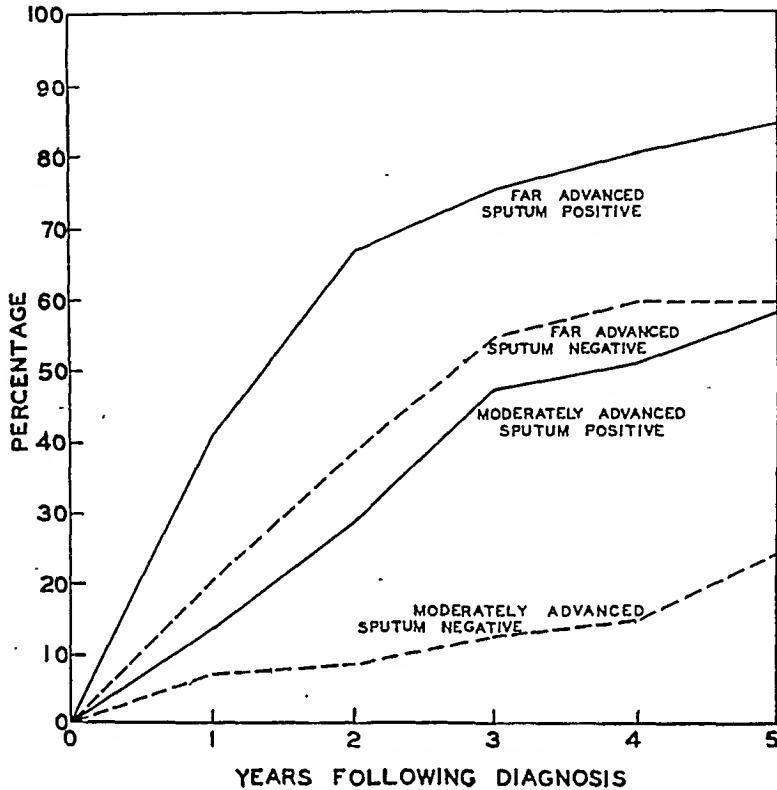

TABLE 6

Cumulative Mortality, per 100, of Active White Cases with Moderately Advanced and Far Advanced Lesions, According to Sputum on Diagnosis

Years Following Diagnosis	Moderately Advanced		Far Advanced	
	Sputum Positive	Sputum Negative	Sputum Positive	Sputum Negative
1st	13.7	7.1	41.2	20.2
2nd	28.5	8.5	67.0	38.6
3rd	47.0	12.3	75.2	54.7
4th	51.4	14.8	80.7	60.0
5th	58.3	24.3	84.6	60.0

FIG. II

CUMULATIVE MORTALITY PER 100 OF ACTIVE WHITE CASES
WITH MODERATELY ADVANCED AND FAR ADVANCED LESIONS
ACCORDING TO SPUTUM ON DIAGNOSIS

positive sputum the mortality was great, with 41.2 per cent dead by the end of the first year and 84.6 per cent by the end of the fifth. Among those with negative sputum, the percentages were lower, 20.2 and 60.0, respectively. Thus, it is shown that the risk of death is much greater for those with positive sputum at the time of diagnosis than for those with negative sputum, in both moderately and far advanced groups.

Hilleboe⁴ has published data regarding survival rates from which cumulative mortality according to extent of lesion and sputum status was obtained for persons discharged from public sanatoria in Minnesota. Mortality rates based on observations from date of discharge from sanatoria exclude many

deaths which are included when observation begins with date of diagnosis. The mortality experience of patients discharged with moderately advanced lesions and positive sputum from 12 rural sanatoria in Minnesota was, however, similar to that observed in Tennessee for cases moderately advanced and with positive sputum at the time of diagnosis. By the end of the first year, 17.5 per cent of the Minnesota patients were dead and 13.7 per cent of those in Tennessee; by the end of the fifth year, the percentage dead was 57.8 for Minnesota and 58.3 for Tennessee. Among the patients with far advanced disease and positive sputum, the mortality was greater for those in Tennessee than for those in Minnesota.

HOSPITALIZATION AND PNEUMOTHORAX TREATMENT

The only county sanatoria in Tennessee are located in the four counties containing large cities, and admit only residents of those counties. For the population served by the field diagnostic units, hospital facilities are limited, with the result that in only a small percentage of cases is such care received during the first year following diagnosis. Since July 1, 1939, a program has been in effect whereby the state pays half the daily rate in general hospitals or in private sanatoria and local agencies the balance to hospitalize indigent patients suitable for collapse therapy. The number and percentage of white persons hospitalized for tuberculosis and the number and percentage receiving pneumothorax treatment during the first year following diagnosis, by year of diagnosis, are shown in Table 7.*

year following diagnosis. Pneumothorax treatment was stated as being received by only 5 patients diagnosed in 1937; by 1940, this number had increased to 55. In view of the difficulties encountered in securing pneumothorax treatment and hospital care for patients in the rural areas of the state, these results are encouraging.

Many factors are responsible for the increase in percentage of patients receiving hospital care and pneumothorax treatment. The local health officers and nurses do much to interest the patient in obtaining some form of collapse therapy and to arrange ways and means. The clinicians of the diagnostic units consult with the local physicians concerning treatment of the cases. Educational measures, as well as the recent state hospitalization program, are responsible for increases in the numbers of patients receiving such care.

TABLE 7

Number and Percentage of White Patients Hospitalized for Tuberculosis and Number and Percentage Receiving Pneumothorax Treatment During the First Year Following Diagnosis, by Year of Diagnosis

Year of Diagnosis	Total Patients	Hospitalized		Pneumothorax	
		Number	Per cent	Number	Per cent
1936	380	13	3.4	*	*
1937	690	27	3.9	5	0.7
1938	615	35	5.7	24	3.9
1939	611	38	6.2	33	5.4
1940	624	60	9.6	55	8.8

* Not available

Only 13, or 3.4 per cent, of the 380 white patients diagnosed in 1936 entered a hospital for treatment of tuberculosis within a year of diagnosis. By 1940, however, 60, or 9.6 per cent, received hospital care during the first

SUMMARY

1. Results of observations of tuberculosis patients followed from a few months to five years from date of diagnosis are presented for 5,056 white and 599 colored cases diagnosed in field clinics in the rural areas of Tennessee.

2. Among patients with active tuberculosis the actual number of deaths from all causes was larger than the number expected. Arrested lesions, however, did not affect mortality appreciably in either the white or the colored group.

3. The risk of death was much greater for patients with positive sputum at the time of diagnosis than for those with negative sputum, in both the moderately advanced and far advanced groups.

* Data are presented for white cases only since the number of colored cases in which such care was received was too small for discussion. In considering hospitalization, patients who removed from the county to enter a hospital for treatment of tuberculosis have been included, since information concerning their status, etc., was obtained from the family. Persons who removed from observation during the first year are not included in the totals for each year.

4. The percentage of patients hospitalized and the percentage receiving pneumothorax treatment within the first year following diagnosis were small but increased each year.

DEATH rates from tuberculosis are known to be very high in many of the southern states.^{1, 2, 3} These high rates are in part due to the racial composition of the population since the colored population is largely concentrated in the South and the tuberculosis death rates in the colored population are two or three times the rates in the white population. The rates in the white population are also high in certain southern states with exceedingly high rates in the older age groups. Questions are often raised regarding the accuracy of classification of the cause of death for persons in the older age groups. Do these people actually die from tuberculosis?

The purpose of this report is to compare tuberculosis mortality in Tennessee and the United States and to present an analysis of the data which have been collected regarding tuberculosis deaths officially recorded as such for the 10 year period 1932-1941 for Williamson County, Tennessee. Evidence obtained through clinical and x-ray examination, sputum analysis, and by direct observa-

tion is available for over three-fourths of the persons officially recorded as having died from tuberculosis in Williamson County.

DEMOGRAPHICAL EVIDENCE

In the comparison of tuberculosis mortality, the death rates for the United States for 1939 and for Tennessee for the 3 year period centering in 1939 have been calculated.

The crude white tuberculosis death rate for Tennessee of 60.0 per 100,000 population was 59 per cent higher than the rate of 37.7 for the United States. The difference was even greater when the Tennessee death rate was adjusted for the age distribution of the population of the United States, resulting in a rate of 66.5 per 100,000 population. In the United States as a whole the white male death rate of 44.7 was higher than the white female rate of 30.6, while in Tennessee the opposite was true with the female rate of 62.2 slightly higher than the male rate of 57.8 per 100,000 population. The white female death rate in Tennessee of 68.4, adjusted to the age distribution of the white female population of the United States, was over twice as high as the white female rate of 30.6 for the United States, while the adjusted white male rate in Tennessee of 64.7 was 45 per cent higher than that for the United States. The

55-64 years	97.5	40.8	184.3	107.4
65-74 years	101.1	58.6	136.7	81.3
75 years and over	90.7	73.1	112.0	75.2

Tennessee colored tuberculosis death rate of 159.3, adjusted to the age distribution of the colored population of the United States, was only 24 per cent higher than the rate of 128.9 for the United States. Therefore, it is evident that the excessive tuberculosis mortality in Tennessee is chiefly in the white population, with a greater excess among females.

To show the age groups of excessive mortality, the death rates have been calculated by age, sex, and color. In Table 1 and Chart I-A are given these rates for the United States.

The white male tuberculosis death rates increased with age to the high rate of 101.1 per 100,000 population for those 65-74 years of age while the female rates were high for young adults 20-34

TUBERCULOSIS DEATH RATES PER 100,000 POPULATION BY AGE, SEX AND COLOR FOR UNITED STATES AND TENNESSEE

years, followed by a slight decrease for females 35-54 years, with an increase to the rate of 73.1 for females 75 years and over. Among colored males the rates were high for young adults and continued high with a decline for colored males 55 years and over. Very high rates were recorded for young colored females 20-29 years of age followed by lower rates in the older age groups.

The tuberculosis death rates are given in Table 2 and Chart I-B for Tennessee for the 3 year period * 1938-1940.

States, the distributions of these rates, by age, were similar.

On subdivision of these data for Tennessee by urban and rural areas it was found that the white tuberculosis death rate in the rural area was higher than the rate in the urban area, with a marked excess in the older age group. The colored tuberculosis rate, however, was higher in the urban area than in the rural area.⁴

Without doubt the outstanding feature in the comparison of mortality from tuberculosis in Tennessee and the United

* Adjusted for age distribution of population of United States, 1939

In the white population the death rates for both male and female increased with age and were very high for those 55 years and over. Both male and female death rates were higher in Tennessee than in the United States for young adults and for those in the older age groups. The excessive mortality was greater for white females than for white males. Although the colored male and female death rates were higher in Tennessee than they were in the United

States is the very high rate in Tennessee in the white population in the older age groups, that is, for those 55 years of age and over.

In considering the high tuberculosis death rates in the older age groups in Tennessee the study of the rates in the past would be enlightening. These people dying in the older age groups have no doubt passed through a period when tuberculosis death rates were higher than they are at present. The sizes of such rates are not known since official reporting of deaths on a state-wide basis in Tennessee dates back only to 1914. The late Dr. W. H. Frost made the

* Since the numbers of deaths in the various age groups in Tennessee were small, average rates for the 3 year period, 1938-1940, were obtained.

following statements⁵ regarding the relatively high mortality rates in the older age groups:

Viewed in this light the relatively high mortality rates now exhibited in the higher age groups seem to me to have a significance quite different from what I had attributed to them. They may be interpreted as the residuum of the much higher rates which the now aged cohorts have experienced in earlier life. In general, the rule seems to be that the higher the mortality of any cohort in early life, the higher will it be in later years. Or, to have passed through a period of high mortality risk confers not protection, but added hazard in late life.

Study of the tuberculosis deaths reported since the beginning of the Williamson County Tuberculosis Study in

During the 10 year period, 1932-1941, 214 tuberculosis deaths have been recorded for Williamson County.* The average tuberculosis death rate for this period was 87.5 per 100,000 population with the colored rate of 172.4 nearly three times the white rate of 62.8.

A slight decrease has been noted in both white and colored death rates as shown in Table 3.

Of the 214 tuberculosis deaths recorded for Williamson County, 140 were deaths of persons followed in the study who were known to have died from tuberculosis, 47 were believed to be tuberculosis deaths upon investigation, 23 were considered deaths from causes

75 years and over	7	383.6	9	477.5	1	200.0

In addition to these 214 deaths recorded as tuberculosis, 33 other patients with active tuberculosis were followed in the study and were known to have died from the disease. The causes of deaths for 18 of these patients were stated to be other than tuberculosis on death certificates, no death certificate was recorded for 8, and death certificates were filed for other areas with the residence stated incorrectly or were filed late for 7. When these additional tuberculosis deaths, 33, were added to the

number of deaths officially recorded as tuberculosis and considered so by the study, 187, the total number of deaths considered caused by tuberculosis was 220. This number is practically the same as the number officially recorded as tuberculosis deaths due to the subtraction of 27 and addition of 33. Thus in considering the number of the tuberculosis deaths in Williamson County, it appears to be approximately the same as the number officially recorded.

These 220 deaths considered caused

TUBERCULOSIS DEATH RATES PER 100,000 POPULATION BY AGE, SEX AND COLOR FOR WILLIAMSON COUNTY AND TENNESSEE

by tuberculosis will be used in the following discussion. The average tuberculosis death rates by age, sex, and color have been calculated to compare with the rates in Tennessee. The data for this 10 year period for Williamson County are given in Table 5.

In Chart II these rates are shown graphically with average data for Tennessee for the 3 year period, 1935-1937, for comparison. With the small number of deaths involved for Williamson County for some of these age groups, the consistency of Williamson County rates with those in Tennessee seems noteworthy. The death rates in the white population in the older age groups are high in Williamson County as they are in Tennessee, with the female death rate higher than the male death rate. Therefore, the tuberculosis death rates by age, sex, and color in Williamson County are found to be essentially in agreement with those in Tennessee.

CLINICAL EVIDENCE

Of the 220 deaths considered attributable to tuberculosis, 173 were of patients followed in the study. The remaining 47 deaths were investigated after death with inquiry regarding symptoms and duration of illness. It is possible, therefore, to give additional data regarding the nature and evidence of the disease for the 173 persons followed in the study.

Diagnoses of tuberculosis have usually

been established by physical and x-ray examinations. Suspected cases of tuberculosis have been referred to the clinic by the private physicians of the county and the diagnoses have been made by the study clinician. Whenever the patient has been too ill to be brought to the clinic an examination has been made in the home. If electric current was available, portable equipment was taken to the home so that the x-ray might be made. In a few cases the clinician has gone to the home with the private physician to examine a very sick patient. Following initial examination, nursing visits and periodic examinations have been made according to the recommendations of the clinician.

In Table 6 are given the numbers of diagnoses established by x-ray examination by age group and color.

Diagnoses of 86 per cent of the white and 92 per cent of the colored cases were established by x-ray examination. Of the 14 white patients without x-ray examination, 10 submitted sputa which were positive. Three of the other 4 had far advanced bilateral tuberculosis and died within a few months after examination. The 4th was a bed patient with moderately advanced tuberculosis and died 2 weeks after examination.

Of the 6 colored patients without x-ray examination 4 had positive sputa and the other 2 had far advanced bilateral tuberculosis, and both died within 1 month after examination.

TABLE 6

Diagnoses Established by X-ray Examination for 173 Patients Dying from Tuberculosis, by Age and Color, Williamson County, Tenn., 1932-1941

Age Group	White			Colored		
	Diagnoses Established by X-ray Examination			Diagnoses Established by X-ray Examination		
	Total	Number	Per cent	Total	Number	Per cent
Total	97	83	86	76	70	92
Under 15 years	3	3	100	9	9	100
15-34 years	32	28	88	36	33	92
35-54 years	24	21	88	24	22	92
55 years and over	38	31	82	7	6	86

The 97 white patients were given 255 x-ray examinations and 51 physical examinations in the home so that they had on the average 3.2 examinations. Each of the 76 colored patients had an average of 2.6 examinations.

In studying duration of the disease, the length of time from onset of the disease as manifest by symptoms to death has been obtained for each patient. The average years from onset of first symptoms to death from the disease according to age and sex of white persons dying from tuberculosis are given in Table 7.

that for white persons. Among the colored, the period from onset to death was 2.3 years for the male and 1.6 for the female. The longer period of time from onset to death for colored males than for females is consistent with the tuberculosis death rates which indicate that males dying from tuberculosis live longer than do females.

Of the 38 white persons in the older age group (55 years and over), 11 were 55-64 years, 18 were 65-74 years, and 9 were 75 years of age or over. It should be pointed out that this large number of old people with the disease

TABLE 7

Average Years from Onset to Death of White Persons Dying from Tuberculosis, by Age Group and Sex, Williamson County, Tenn., 1932-1941

Age Group	Total		Male		Female	
	Number	Average Years from Onset to Death	Number	Average Years from Onset to Death	Number	Average Years from Onset to Death
Total	97	8.7	43	9.0	54	8.5

35-54 years	24	9.3	10	10.6	14	8.4
55 years and over	38	14.0	20	12.4	18	15.8

The average period of time for white persons dying from tuberculosis, that is, from onset to death, was 8.7 years. For those 55 years of age and over, the average period, 14.0 years, was longer than for the younger adults. The length of time from onset to death for colored persons (1.8 years) as shown in Table 8 was approximately one-fifth

over relatively long periods of time may play an important part in keeping the tuberculosis death rates high in Tennessee. These old people have the disease many years and are not sufficiently disabled to be bedridden. Some of them live in several households with sons and daughters and grandchildren. Therefore, over a long period of time

TABLE 8

Average Years from Onset to Death of Colored Persons Dying from Tuberculosis by Age Group and Sex, Williamson County, Tenn., 1932-1941

Age Group	Total		Male		Female	
	Number	Average Years from Onset to Death	Number	Average Years from Onset to Death	Number	Average Years from Onset to Death

55 years and over	7	3.5	6	1.6	1	15.1

the disease may be spread by them to many young people. Some of the young susceptible individuals in contact with parents or grandparents with tubercle bacilli in the sputum break down with the disease and die from tuberculosis while others are resistant and the tuberculous process becomes arrested. Cases of this second type may break down many years later. An example in which the grandmother in the family had chronic tuberculosis with little disability is given as an illustration.

The head of the family, a white male, age 38, with symptoms of tuberculosis, was referred to the study by his private physician. On x-ray examination he was found to have far advanced tuberculosis with tubercle bacilli in the sputum. This man died 2 years and

was also found to have moderately advanced tuberculosis with tubercle bacilli in the sputum and she died one year and one month later. In addition, another son of the grandmother in the family died from tuberculosis in 1913, age 22 years. Thus this old lady lived for many years probably expectorating tubercle bacilli occasionally which, in turn, caused new cases and deaths in the family. These 3 additional cases and deaths occurred in a period of 23 years.

BACTERIOLOGICAL EVIDENCE

Another evidence of tuberculous disease among these patients carried prior to death was obtained through sputum analyses. The results of such examinations are given in Table 9.

TABLE 9

Results of Sputum Analysis for 173 Patients Dying from Tuberculosis by Color and Age, Williamson County, Tenn., 1932-1941

5 months later of tuberculosis. On examination of other members of the family, his mother, age 77 years, was found to have far advanced tuberculosis. Tubercle bacilli could not be isolated from the five specimens of her sputum submitted. According to the history obtained, this woman had a prolonged cough for 1 year with expectoration in the morning, about 50 years prior to examination. Although she had symptoms and physical signs of tuberculosis at the time of examination, she was only slightly disabled. She died 3 years and 4 months later from tuberculosis. The daughter of the head of the family who was 14 years of age

Of the 173 patients who died from tuberculosis and were followed in the study, 132, or 76 per cent, were known to have been discharging tubercle bacilli. For all adult age groups, the proportions of these persons found to have tubercle bacilli in the sputum were high and this is confirmatory evidence of tuberculous disease. For 23 patients, specimens could not be obtained and for 18 the specimens submitted were negative for tubercle bacilli.

Some of these persons, with tuberculosis over a long period of time, especially in the higher age groups, were known to have tubercle bacilli in their sputum for many years. An example

of such a case was a white male, 66 years of age on examination, who was found to have far advanced tuberculosis with cavitation. The onset of the disease occurred 3 years prior to examination. His condition remained practically the same for 6 years. Sputum analyses were made on 56 occasions and all were positive. During most of this time he felt well and was able to be up every day. He died from the disease 9 years after onset of first symptoms.

Although 31 of the 45 patients in the older age group (55 years and over) were found to have tubercle bacilli in their sputa, specimens submitted on two or more occasions for 9 were negative. No doubt through examination of additional specimens of these patients, tubercle bacilli would have been isolated for a few.* Of these 9, 8 were white females who were known to have had the disease for 20 years, on the average. Their average age at death was 73 years. Five had far advanced and 4 moderately advanced tuberculosis on x-ray examination and very little disability. Clinical and x-ray examination showed that these people had active disease which caused death. An illustration of this type of case is the grandmother in the white family discussed previously. Only one specimen was obtained at the time of death and four others were obtained 1-4 years prior to death. Examination revealed strand-like infiltration throughout the entire right lung with bronchiectasis in the base, also strand-like infiltration in the circle of the first rib in the left lung with calcium in both lungs. Pulmonary

symptoms became worse for the last few months prior to death and her death was attributed to tuberculosis.

These sputum findings offer additional evidence of the accuracy of the classification of the causes of death as tuberculosis.

SUMMARY

1. The tuberculosis death rates for Tennessee have been compared with those in the United States. The outstanding feature of the difference was the very high rates in Tennessee in the white population in the older age groups, that is, for those 55 years of age and over.

2. During the 10 year period 1932-1941, 214 tuberculosis deaths were recorded in Williamson County. This number of officially recorded deaths appears to be practically the same as the total number of deaths, 220, considered upon investigation as due to tuberculosis.

3. On studying the Williamson County tuberculosis death rates by age, sex, and color, the rates were found to be essentially in agreement with those in Tennessee with high rates in the white population in the older age groups.

4. Diagnoses have usually been established by x-ray, with 86 per cent of the diagnoses of the white and 92 per cent of the colored patients dying from tuberculosis established in this way.

5. The duration of the disease, from onset of first symptoms to death, was 8.7 years for the white patients followed in the study and 1.8 years for the colored patients.

6. For these patients who died from tuberculosis and were carried in the study, 76 per cent were known to have been discharging tubercle bacilli prior to death. This was additional evidence of the accuracy of the classification of the causes of death as tuberculosis.

* Sputum of one of the females with far advanced tuberculosis who had 10 negative sputum examinations in the study was examined by Dr. B. J. Olson of the National Institute of Health. Although the smear and culture were negative, 1 out of 4 animals inoculated with undigested sputum showed evidence of the disease on autopsy. This sputum was examined 3 months prior to death and 3 months after the last sputum examination in the study.

Prevalence and Incidence of Tuberculosis among Household Associates According to Age and Sex of Index Case*

HOWARD C. STEWART, M.D., DR.P.H., F.A.P.H.A., R. S. GASS, M.D., AND W. C. WILLIAMS, M.D., F.A.P.H.A.

Tennessee Department of Public Health, Nashville, Tenn.

THE occurrence of manifest tuberculosis in household associates of sputum-positive or presumably sputum-positive index cases and in associates of cases other than sputum-positive in Williamson County, Tenn., has been previously reported.^{1, 2, 3} In none of these reports was there any division of material according to the sex and age of the index case. It seems likely that these factors are of importance in determining the risk of development of manifest tuberculosis in household associates. The age at which tuberculosis develops may influence the type of disease and the rapidity of its course; these in turn may affect materially the extent and the duration of the exposure to which associates are subjected. Exposure may be affected also by varying intimacy of contact, since, for example, the relationship between young children and their parents is in general closer than between such children and their grandparents.

If the age of the index case is a significant factor, Tennessee data should be of especial interest. From age-specific tuberculosis death rates it has been learned that Tennessee, in the white portion of its population, presents a picture quite different from that of the United States in two respects:

1. In the older ages the rates for Tennessee have been much higher for both sexes.

2. In these older ages the rates for females have been higher than for males while in the United States the rates for males have been higher than for females.

In certain acute diseases there are peculiarities of secondary attack rates which may be attributable to the age of the primary case. In diphtheria, for example, studies of familial incidence show higher attack rates among adolescent and younger adult females than among males of comparable ages.⁴

It should be remembered that the index case is not necessarily the first case in the household. Not infrequently cases found as a result of examination of household associates give histories of onset of illness which antedate that of the index cases, sometimes by many years. Usually, however, the index case is the first recognized case in the household.

* Presented before the Epidemiology Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

This investigation was made possible by the financial support of the International Health Division of the Rockefeller Foundation.

Acknowledgment is made of the valuable suggestions made by Dr. J. A. Doull in the preparation of this report.

With these facts in mind prevalence and incidence of tuberculous lesions have been studied according to the age and sex distribution both of index cases and of household associates. The practical questions on which it is hoped eventually to throw light may be expressed as follows: (a) Does age and sex of the index case affect the prevalence of tuberculosis among household associates at the time the household comes to the attention of the health department? (b) Does age and sex of the index case affect significantly the incidence of tuberculosis among household associates in subsequent years?

NUMBERS OF INDEX CASES AND ASSOCIATES

From the beginning of the intensive study of tuberculosis in Williamson County late in 1931 through December 31, 1940, 536 white individuals with some form of reinfection tuberculosis have been designated as index cases in white households. These 536 white index cases and their household associates form the basis for the present analysis. A diagnosis of manifest tuberculosis is based upon evidence of tuberculosis recognizable by history or physical examination. The cases of manifest tuberculosis have been divided in two groups:

1. "Sputum-positive," including those with tubercle bacilli demonstrated on two or more occasions by staining untreated sputum, those fatal before investigation and those with insufficient or no sputum analysis dying shortly after observation was commenced.

2. "Other manifest," including those sputum-negative on two or more examinations, and those with insufficient or no sputum analysis not falling in the first group with respect to death.

Those with apical lesions demonstrable by x-ray, but without associated physical signs, symptoms, or history which would lead to the diagnosis of tuberculosis in the absence of x-ray examination were classed as "latent apical."

In the classification of findings in household associates, the same criteria have been used as for the index cases. Those with no evidence of reinfection tuberculosis have been classed in two groups:

1. Primary tuberculosis, including those who, on x-ray examination, show nothing more than a lesion of the primary or first infection type, with no signs or symptoms of tuberculous disease.

2. Negative, including those who, on physical and x-ray examination show no signs of tuberculosis, but not necessarily a negative tuberculin reaction.

The distribution of index cases by type, sex and broad age groups is shown in Table 1.

Of 536 index cases, 322, or 60 per cent, were females. For all types, this excess of females was most striking in those under 35 years of age, but it is evident also in those of 35 to 54 years of age. In the oldest age group, 55 years and over, the numbers of males and females are approximately equal. It is of special interest that of 46

TABLE 1

sputum-positive or fatal index cases in persons 55 years of age and over, 30, or 65 per cent, were males.

The higher mortality among females in the older ages has already been mentioned. This has been a feature of

with those cases found as the result of examination of household associates of index cases. There were 74 manifest cases and 63 latent apical cases of tuberculosis in the latter group and the comparison is shown in Table 2.

tuberculosis mortality of this state in every year since data have become available but this disparity between the sexes has not been so apparent in recent years. At ages under 35 years, the death rates for females have continued to remain substantially higher than those for males. This is, however, an almost universal feature of mortality from tuberculosis. In Tennessee as a whole, judging from response to the field diagnostic service of the Division of Tuberculosis Control, females are more likely to report to physicians or clinics for chest examination and to report sooner after appearance of symptoms than males. Males are more apt to disregard symptoms and delay examination. It is, therefore, not surprising to find an excess of females among index cases in Williamson County.

SEX AND AGE DISTRIBUTION OF INDEX CASES AND OF CASES FOUND AMONG HOUSEHOLD ASSOCIATES

It is of some interest to compare the sex and age distribution of index cases

These added cases of manifest tuberculosis had a slightly greater proportion in the age group 55 years or over than the index cases. The added latent apical cases had a somewhat different age distribution, with proportionately a larger number at ages less than 35 years.

The sex distribution of these added cases was quite similar to that of the index cases, 57 per cent being females.

PREVALENCE OF TUBERCULOSIS IN HOUSEHOLD ASSOCIATES

In Williamson County, as in the state as a whole, it has been possible to examine a larger proportion of female household associates than of male associates. For a variety of reasons females report to the family physicians or to the clinic more promptly and, in a greater proportion of instances, after an examination has been recommended than do males. A difference in the sense of economic pressure is probably of importance, and it is also likely that nurses are able to impress on females the advisability of examination to a

greater extent because most of the home conversations of the nurse are with the females of the household. The approach of the nurse is, therefore, more likely to be direct in dealing with females than is the case with males.

In determining the prevalence of tuberculous lesions among household associates according to type, sex, and age of the index case an adjustment for age was found to be advisable. The prevalence rates of tuberculous lesions shown in Tables 3 and 4 have been adjusted to the age distribution of all household associates.

Prevalence according to age of index case—Table 3 shows the prevalence of tuberculous lesions by sex among household associates according to age group and classification of the index case. Among household associates of sputum-positive index cases no significant variation in prevalence of manifest disease was associated with differences in age. For associates of index cases under 55 years of age the prevalence rate was 6.7 per cent, and for associates of older index cases it was 6.3 per cent. For the other than sputum-positive group there was an apparently higher rate, 3.3 per cent, when the index cases were under 55 years of age, than when they

were older, 1.2 per cent, but the difference may have been a fortuitous one.

Of male associates of sputum-positive cases under 55 years of age, 6.4 per cent were found to have manifest tuberculosis, and of the comparable female associates, 7.2 per cent. A wider difference, however, was found among associates of this type of index case older than 55 years. Of the males the proportion found to have manifest tuberculosis was 2.4 per cent and of the females, 8.7 per cent. From this it is suggested that, among associates of older index cases of the sputum-positive class, tuberculosis was much more frequently found in females than in males, whereas in the households of younger index cases, there was little difference between the prevalence rates for males and females.

This higher proportion of females showing manifest tuberculosis was seen also in household associates of the older index cases other than sputum-positive. The proportion of male associates of this type of index case under 55 years of age found to have manifest tuberculosis was 3.0 per cent, and for females the proportion was 3.7 per cent. Among associates of this type of index case 55 years of age or over, 0.3 per cent of

males, and 1.9 per cent of females were found to have manifest tuberculosis.

The proportions of associates found to be negative for any type of tuberculous lesion on x-ray examination when compared by sex are the reverse of those noted to have manifest tuberculosis. In each class a smaller proportion of females was negative.

Although prevalence rates of manifest tuberculosis were approximately the same in the two groups of associates of sputum-positive index cases when comparison is made by age of the index case, the proportion of associates of the older index cases with no evidence of tuberculous infection was higher than for associates of index cases of younger ages (27.2 per cent and 16.9 per cent). This difference may be attributable to lesser intimacy of contact between older cases and others in the household, especially children.

Prevalence according to sex of index case—The prevalence of tuberculosis lesions of various types among associates according to type and sex of the index case is shown in Table 4.

In the sputum-positive type, the associates of male index cases had an appar-

ently higher prevalence rate (8.5 per cent) than had associates of female index cases (5.1 per cent). The associates of other than sputum-positive index cases showed no significant difference related to the sex of the index case. Also the proportions escaping infection, as judged from x-ray examinations, were approximately the same regardless of the sex of the index case.

It is also of interest that when the index case was male the prevalence rate for males (7.5 per cent) was not widely different from that for females (9.7 per cent). But when the index case was female the rate for males (3.4 per cent) was lower than that for females (6.5 per cent).

INCIDENCE OF NEW CASES OF TUBERCULOSIS

The incidence of new cases, by sex, during the period of observation, is shown in Tables 5 and 6.

Incidence according to age of index case—The first division of the material is according to type and age of the index case and is given in Table 5. Among household associates of sputum-positive index cases under 55 years of age the

TABLE 5

New Cases of Tuberculosis by Sex with Rates per 1,000 Among Household Associates According to Age Group and Classification of Index Case

	Total			Male			Female

	Person-Years	Number	Rate	Person-Years	Number	Rate	Person-Years	Number	Rate
<i>Associates of Sputum-Positive Index Cases</i>									
Total	2,364.75	18	7.6	1,235.75	9	7.3	1,129.00	9	8.0
Index Cases under 55 years	1,644.75	15	9.1	905.50	8	8.8	739.25	7	9.5
Index Cases 55 years and over	720.00	3	4.2	330.25	1	3.0	389.75	2	5.1
<i>Associates of Other Than Sputum-Positive Index Cases</i>									
Total	7,122.00	17	2.4	3,885.50	8	2.1	3,236.50	9	2.8
Index Cases under 55 years	5,100.50	16	3.1	2,804.75	8	2.9	2,295.75	8	3.5
Index Cases 55 years and over	2,021.50	1	0.5	1,080.75	940.75	1	1.1

incidence rate was 9.1 per 1,000 during the period of observation, while in associates of this type of index case of 55 years and over, only 4.2 per 1,000 developed manifest tuberculosis. Corresponding rates for associates of cases other than sputum-positive were 3.1 and 0.5. The numbers of cases in certain of the classes are small but it is of interest that the difference is in the same direction for associates of both classes of index cases, namely toward more tuberculosis in the households of younger index cases. If the risk is actually greater when the index case is younger, however, significant differences in prevalence as well as incidence would be expected. Final judgment on this question, therefore, must await a larger experience.

Incidence according to sex of index case—The material has been divided also by type and sex of the index case and the respective attack rates are given in Table 6.

Associates of female index cases had noticeably higher incidence rates than associates of male index cases. Among associates of sputum-positive index cases the incidence rate for associates of male index cases was 3.0 per 1,000 and for associates of female index cases 11.1 per 1,000. Associates of index cases other than sputum-positive had lower incidence rates; for associates of male index cases the rate was 1.2 per 1,000 and for associates of female cases it was 2.8 per 1,000. In each class of index case the highest incidence rate was noted in female associates of

Male Index Case	2,707.50	5	1.8	1,162.25	2	1.7	1,545.25	3	1.9
Female Index Case	4,414.50	12	2.7	2,723.25	6	2.2	1,691.25	6	3.5

female index cases, this rate being 14.3 per 1,000 for female associates of female sputum-positive index cases. The next highest rate 8.8 per 1,000 was observed in male associates of female sputum-positive index cases. Caution must again be observed since it is not clear why a significant difference in incidence would not be reflected in higher prevalence among associates of female index cases.

There is, however, a suggestion that the risk of developing tuberculosis may be higher where associates are exposed to index cases under 55 years of age than when the index cases are older. Also it is suggested that the risk is greater for associates of female index cases than for associates of male index cases. Unfortunately the problem has certain complications which available material cannot resolve. In the sputum-positive class the average age of female index cases was 39 years, that of male 51 years; and in the other than sputum-positive, the respective averages were 44 years and 48 years. Thus, if there is a significant factor it may be either the age or the sex of the index case, or possibly both.

A second complication in interpretation is that neither the age nor the sex of the index case was closely related to variations in prevalence of manifest tuberculosis among household associates.

It is of interest that, regardless of the type, age, or sex of the index case, prevalence and incidence rates were higher for female than for male associates. This may be interpreted as reflecting a closer relationship between females in the household and the patient, or on the other hand it may reflect greater susceptibility of female

associates. The finding of higher prevalence among females than males when the index cases were over 55 years of age but a smaller excess when index cases were younger is in need of confirmation. If true, the explanation may indeed be more continuous association of females with tuberculous patients, that is, greater exposure of female associates.

SUMMARY

1. Prevalence and incidence of tuberculosis morbidity in household associates, by sex, have been determined for different classes of index cases according to age and sex of the index cases.

2. Among index cases, females were more numerous than males. This was also true for those cases found as the result of examination of household contacts.

3. Among household associates a higher proportion of females was found to have manifest tuberculosis, and a smaller proportion of females escaped tuberculous infection.

4. Prevalence and incidence rates were somewhat higher among associates of index cases under 55 years of age than among associates of index cases 55 years of age or over.

5. The risk of development of manifest tuberculosis appeared to be greater among associates of female index cases and this risk seemed to be greater in female than in male associates. Available data are, however, too limited to allow a final judgment on the importance of sex of the index case. Such judgment must await accumulation of a larger body of data.

Simplification of Laboratory Control Procedures for Market Milk*

ROBERT S. BREED, PH.D., F.A.P.H.A.

New York Agricultural Experiment Station, Geneva, N. Y.

THE effort to simplify the procedures used to determine the quality of market milk has gone on continuously for many years. It has, nevertheless, received an added stimulus because of the present war emergency. Laboratory men have made real progress in the development of simplified tests during the past few years, and can apparently point with pride to results accomplished. Milk sanitarians who have tried to hold milk inspection procedures to essentials without unnecessary duplications in farm and milk plant inspections can also feel that progress has been made although the dairy farmer and the industry are still plagued with a multiplicity of inspections and inspectors. Too frequently regulations are of a type that specifies that construction of barns, milk houses, etc., and cleaning, sterilizing, or other procedures must be carried out in a specific way, whereas the primary function of the inspector should be to see that the consumer receives clean, fresh, safe milk. Both the farmer and the milk plant men frequently know methods of producing milk that meets the standards fixed that are more practical than are the methods specified in regulations; or at least can learn them from agricultural extension agencies, maintained to bring

them the latest and best information in the agricultural field.

Reliance should be placed on tests applied to milk itself, and these tests should be of a type that can be applied before the milk is used. If they can be used by the field, rather than by the laboratory workers, so much the better. Where quality is found to be wanting, the results secured should direct the corrective procedures.

It is not possible to discuss all possible approaches to this problem in the brief time at our disposal, and this paper will be limited to a discussion of methods that seem to be giving good results.

The American Public Health Association Report on Standard Methods for the Examination of Dairy Products offers a wide choice in analytical procedures for determining the quality of milk, both as delivered at receiving stations and as delivered to the consumer. From this report, it is possible to make selections that are suitable for use under widely different local conditions.

METHODS USEFUL IN CONTROLLING THE QUALITY OF RAW MILK AS DELIVERED FOR PASTEURIZATION

Procedures that permit poor quality milk to be recognized and rejected before it is mixed with other milk are the best ones to use at this point. No test has been developed that permits as rapid recognition of poor quality milk as the odor test applied by smelling the inside of the cover as the can is opened

* *Journal Paper No. 546*, Jan. 26, 1943, New York State Experiment Station, Geneva, N. Y. Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

to dump the milk into the weigh vat. This in itself requires no laboratory equipment and the odor can be determined by the trained person as rapidly as the cans can be opened and dumped. Only those who have had experience with it, will realize how effective this time tested and simple procedure can be made. The method has been used by the industry itself ever since milk dealers began to buy milk from producers, but it had never been tried on a large scale by dairy inspectors until a system of deck inspection based on the odor test was put in widespread use in the New York City milk shed in 1937. The odor test is supplemented in this work by an examination with a strainer dipper to detect sediment and flaky milk.

In this discussion of the results secured in this deck inspection control, I shall draw freely on a recent report of this work by R. L. Furnia of the New York City Milk Inspection group.* In 1937, the New York City group of Inspectors put into use the training they had secured in several conferences held at the Experiment Station at Geneva, at the College of Agriculture at Ithaca, in New York City milk plants, and elsewhere. At these conferences, the men who were to do the work had had opportunity to examine cans of milk with known defects in quality until they became confident that they could recognize milk that showed marked defects in quality.

During 1937 these inspectors examined 1,082,497 cans of milk on the receiving platform, rejecting 20,397 cans (1.9 per cent) as unfit for use. Operators of milk plants rejected many more, the figures given including the cans examined by the city inspectors only. The three main causes for rejection were: improper cooling 52 per cent, dirty utensils 16 per cent, and mastitis milk

10 per cent. This work was found to be so valuable that it has been continued.

In 1941, the city inspectors examined 1,341,679 cans of milk on receiving platforms, and rejected 19,260 cans (1.43 per cent). The causes for these rejections were listed as improper cooling 28 per cent, dirty utensils 33 per cent, mastitis milk 14.5 per cent. Because the factors that produce poor quality milk are many and varied, it is not worth while to speculate on the reasons for differences in the results secured.

When a can of milk is rejected, the procedure followed by the New York City Inspection group is to attach a red tag to the can and to check the cause of the rejection on the tag. This can be done readily when the milk is rejected because it is dirty (visible dirt on the strainer dipper), flaky, too warm, or because of odors. However, if the "odor" has caused the rejection, it is necessary to check results by making a direct microscopic examination to determine whether the odor is due to feed or weed odors (ensilage, molasses, wild onions, cabbage, turnips, etc.), to souring of the milk, or to mastitis. All of these things cause readily recognizable odors and the inspector who checks his findings with a microscope soon becomes remarkably accurate in detecting the cause of the odors. In a recent series of 100 cans rejected for bacterial odors, 16 contained the mastitis streptococcus and leucocytes in excessive numbers. The odor of such milk is recognizable and this type of milk represents the most objectionable type of milk received. While it is usually true that the streptococcus found is of the bovine type, in rare cases this may be of the human hemolytic type and capable of causing a virulent septic sore throat or scarlet fever epidemic.

Occasionally the bacteria found may be of the food poisoning staphylococcus type. This was well illustrated by what

* Furnia, R. L. Causes and Reasons for Rejected Milk. 16th Ann. Rep., New York State Assoc. Milk Sanitarians, Sept. 24, 1942.

happened in May, 1942, in the home of a dairyman near Geneva. A can of milk rejected by a New York City Inspector for a bacterial odor was left to stand for 24 hours without refrigeration. Then the cream was removed and used for making homemade ice cream. All of the four children and one adult who partook of the ice cream suffered from typical staphylococcus food poisoning, and examination of the cream showed these organisms to be present.

On another occasion, a prominent dairyman from the same area brought me a sample from a can of rejected milk. He was angry because, as he told me, the inspector had picked only one can as bad out of the 16 sent to the receiving station. All of the cans had been handled in the same way and he was confident that if 15 cans were good, all were good. However, when the milk was examined under the microscope, it was full of mastitis streptococci and the reason for its rejection was obvious. As there was but one cow with a bad quarter, the reason for the rejection of one can only was also evident. Probably a more careful examination on the platform would have revealed a second can that should have been rejected.

While it is not claimed that the rough tests used on the platform with great rapidity yield results that are 100 per cent accurate, a good inspector does not reject milk that ought not to be rejected. He may miss some poor quality milk, but the farmer who tries to get by with careless methods is sure to be caught and caught promptly when the platform inspection is carried out frequently. Skill in this work can be developed readily by any person with a normal sense of smell.

At smaller pasteurizing plants it may be possible to take samples for microscopic examination from each can of milk. This is the procedure followed at the two small plants in Geneva, N. Y. If cans of poor quality milk are found,

an inspection with microscopic examination of the milk is made on the receiving platform the following morning of the milk from the farm that sent the bad milk the previous day. Bad cans of milk are then returned to the dairyman.

I am told that an adaptation of the platform type of inspection based on a preliminary test with methylene blue, with subsequent microscopic examination of rejected milk, is being tried in California at the present time. Such adaptations are practical and bring results that are effective in correcting bad conditions.

PROCEDURES USED IN JUDGING QUALITY OF BOTTLED PASTEURIZED MILK

I shall not need to take up a discussion of the simplified procedures now in use in many places for judging the quality of bottled, pasteurized milk as W. D. Tiedeman, of the New York State Department of Health, one of the pioneers in the use of the phosphatase test, coliform technic, and microscopic examination system for the control of bottled pasteurized milk, is to discuss his experience with these three tests later in this session. Likewise, Dr. Friend Lee Mickle, our presiding officer today, is to discuss his experience in Connecticut with the same "Three Test System" as he has christened it in a paper to be given before the International Association of Milk Sanitarians.

As shown by Burgwald (*J. Dairy Sci.*, 25:1942, 285-291) public health workers generally have found the short New York City phosphatase technic the most satisfactory phosphatase test for use, as it gives results quickly enough to make it possible to place an embargo on milk before use. However, the best evidence indicates that results from any of the four phosphatase technics described in the Appendix to the 8th edition of *Standard Methods for the Examination of Dairy Products* can be depended upon to yield sufficiently accurate results to

be usable. Results secured with these technics duplicate each other excellently where used for checking the pasteurization of milk heated to 143° F. for 30 minutes. Adjustments must be made in standards where higher or lower pasteurization temperatures are in use.

There is good reason for preferring the sodium formate ricinoleate broth test where examinations are to be made of pasteurized milk for bacteria of the coliform-dysentery-typhoid group. Positive results secured from this test should not be regarded as necessarily indicating the presence of coliform bacteria only, because bacteria belonging in the genera *Serratia*, *Proteus*, and *Salmonella* may also ferment formates with the production of visible gas. However, properly pasteurized milk ought not to contain viable organisms belonging to any of these genera in 1 ml. quantities as the milk leaves the pasteurizer.

It is not necessary to use 5 tubes for each of three dilutions, except where it is desired to determine the number of organisms present that will ferment formates with the production of visible gas with a fair degree of exactness. A test of 15 samples made from 1 ml. quantities in 15 different tubes will give more information about a given milk supply than a test made with 15 tubes prepared from one sample. In our experience, when pasteurized milk is contaminated during the bottling process, the contamination is normally bad enough to give positives in all 1 ml. quantities tested. The chief thing to remember in making coliform tests is that, in order to make results significant, samples must be taken at the pasteurizing plant and they must be tested *at once*. Coliform organisms grow so readily in milk that results secured from testing samples of milk that have stood longer than 2 or 3 hours after taking

are always open to question. Likewise bottled milk should be tested within 2 or 3 hours after it is bottled.

Some further experience is needed, before the standard that should be used where direct microscopic counts are made of the number of clumps of bacteria found in pasteurized milk can be fixed. It is clear that practically all of the bacteria killed during pasteurization lose their staining power or disappear completely during pasteurization. The bacteria found in stainable condition in pasteurized milk consist normally of (1) those bacteria that are heat resistant enough to persist through the pasteurization, (2) thermophilic bacteria that may have grown during preheating, filtering, in the foam, or elsewhere; and (3) bacteria added from the utensils with which the milk comes in contact during the bottling process. If the milk stands 24 hours before delivery, growth may also cause an increase in the number of living bacteria present. These problems are discussed by Walter D. Tiedeman.

CONCLUSIONS

In closing, I should like to emphasize again the desirability of basing the entire milk control program on tests of a type that can be applied by the inspector on the spot with subsequent rejection or embargo placed on the milk before use. This sort of a program is possible with the laboratory tests now available *provided* trained and competent inspectors are available. In many cases it may be necessary to carry out laboratory tests for the sake of records or to support actions that may be questioned in court, but it is clear that the best control work is now being done by persons trained and equipped to make tests of milk quality on the spot where the sample is taken.

Laboratory Control of Milk under War Conditions*

A. W. FUCHS, C.E., F.A.P.H.A.

Sanitary Engineer Director in Charge, Milk and Food Unit, Sanitation Section, States Relations Division, U. S. Public Health Service, Washington, D. C.

WITHIN the time allotted I should like to touch briefly on several phases of the influence of the war on milk control.

1. MILK LABORATORY SURVEYS IN WAR AREAS

During the past year Dr. L. A. Black, a bacteriologist of the U. S. Public Health Service, has been making surveys of milk laboratories in defense areas throughout the country to determine whether equipment and procedures employed in bacteriological examinations are in conformity with the *Standard Methods for the Examination of Dairy Products*, and to suggest improvements toward that goal. Uniformity of laboratory technics is considered particularly desirable at this time because the new and sudden concentrations of troops and civilians have brought about a considerable increase in the importation of milk from other milk sheds. It is not the purpose of these surveys to find fault but to be constructively helpful. Laboratories are visited only upon invitation of the state health departments, and survey reports with recommendations are forwarded to the states, with a duplicate copy for the laboratory in question.

To date nearly 300 laboratories have

been surveyed in 39 states, and the first round of surveys will probably be completed within the next few months. In the early surveys the form used was based on the seventh edition of *Standard Methods*, but for the later ones the survey form was revised in accordance with the eighth edition. The form covers details of the bacterial plate counts, the direct microscopic count, the reductase tests, and miscellaneous information, and provides spaces for indicating departures from *Standard Methods*. It should be of value to any laboratory for checking its own technics.

During the survey of each laboratory, observations were made of the equipment, the general preparation and sterilization of material, and of the technics used in the analyses. Correct procedures were demonstrated and suggested, and blank copies of the forms left as a guide. Numerous consultations have been held with municipal, state, Army and Navy officials in the interest of increasing the dependability and accuracy of the results of the bacteriological examination of milk. Many Army Service Command laboratories have been visited, and the directors of these laboratories acquainted with the form being used. The Army has requested permission to reproduce the forms for the use of its laboratories. In many of the states it has been possible to familiarize someone in an official

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

capacity with the details of the required procedures, so that they might consult with the local laboratories in case of need.

It is not my intention to present here the results of the surveys, as these will be available to those who are interested through a paper to be presented by Dr. Black before this Annual Meeting. At this time I wish to highlight two or three conclusions, as follows:

1. Many of the Standard Methods requirements are not being followed. For example, the average milk laboratory in the first 26 states surveyed complied fully with not more than half of the 25 main items into which the plate count Standard Methods were divided. -

2. The survey indicates the need for an adequate system of state approval or licensing of bacteriological milk laboratories. The type of approval now practised in a few states is nominal or based on equipment only, and therefore gives a false sense of security.

3. Consideration should be given to those requirements of Standard Methods which are frequently violated, with a view to revising or deleting those that do not contribute substantially to the reliability of the results.

Plans are being made for continuing the surveys after the completion of the first round, in order to determine the extent of improvement in equipment and procedures. On the second round it is hoped to visit additional laboratories not previously surveyed, and to spend more time at each than was possible on the first round.

2. REVISED ARMY MILK SPECIFICATIONS

Heretofore the Army specifications for Type III pasteurized milk have included rather meager standards for producing farms and no bacterial standard for the milk prior to pasteurization. Type III pasteurized milk is purchased when neither Type II No. 1 nor Type

II No. 2 is available. The production standards for this type of milk have been raised in the revised tentative U. S. Army specifications set forth in the Quartermaster General's *Circular Letter 377*, dated October 5, 1942. The new paragraph reads as follows:

Raw milk for the production of Type III pasteurized milk shall, upon delivery to the pasteurization plant, have an average bacterial plate count of not to exceed 1,000,000 per cc., or a comparable direct microscopic count, or an average reduction time of not less than $3\frac{1}{2}$ hours. It shall be produced on premises on which buildings, installations, equipment, water supply, facilities, methods and procedures incident to the production, handling, storage and transportation of raw milk are such as to assure that there is delivered to the pasteurizing plant a wholesome milk.

While these revised standards leave much to the judgment of Army veterinary inspectors, they reflect the recognition by Army authorities of the need for farm sanitation and farm inspection even for the lowest grade of pasteurized milk acceptable for Army use.

3. NEED FOR BETTER CONTROL OF THE PASTEURIZATION PROCESS

The critical shortage of fluid milk available for Army and civilian use in many sections of the South and West is being overcome to an increasing extent by the diversion of lower grade milk from manufacturing channels. Under such circumstances it will be necessary to maintain safety and wholesomeness largely by more careful control of the pasteurization process.

The laboratory tests ordinarily employed for pasteurized milk fall short of filling this need. They are valuable in furnishing a record of what has happened between inspections, but most of them are of little practical service because the results are not available soon enough to permit the condemnation of contaminated or improperly pasteurized milk. This is true of the plate count, the coliform count, and of the various

phosphatase tests, except the Scharer field test.

We all recognize the fundamental principle of public health that an ounce of prevention is worth a pound of cure. Let us prevent those hazards to which the pasteurization process is still heir

by developing and utilizing speedy tests, the results of which are available in time to keep unsafe milk off the market. In the meanwhile the best preventive measure lies in more frequent and more careful inspection of plant equipment and procedures.

Laboratory Control of Milk under War Conditions^{*†}

C. K. JOHNS, PH.D.

*Division of Bacteriology and Dairy Research, Science Service,
Department of Agriculture, Ottawa, Ont., Canada*

THE present emergency is forcing us to reëxamine many of our activities and to ask ourselves whether we can get the information we want with less trouble and expense than with our customary procedure.

It is generally agreed that milk for pasteurization should be reasonably free from sediment and have a reasonably low bacterial content. In addition, freedom from excessive numbers of thermoduric bacteria is being stressed in certain areas. Milk as the secretion of a healthy udder is, however, receiving far less attention than it deserves.

The ideal test is unquestionably one which will enable the instantaneous recognition of unacceptable milk. Such a test has yet to be devised. Even the odor test was shown by Schacht and Nichols¹⁶ to detect only a small fraction of the poor quality milk. Platform tests must therefore be supplemented by some other test. Particularly under the present circumstances, with growing shortages of technicians, supplies and equipment, there is much to be said for the use of one of the dye reduction tests. Such tests will vary in the amount of information furnished, but any one of them can form the basis for a quality control program.

Of these tests, the methylene blue reduction test is the most widely used. It has considerable appeal because of its simplicity. When the creaming error is minimized by periodical inversion of the tubes to re-distribute the bacteria in the cream layer^{4, 6, 17} it correlates reasonably well with the bacterial content as revealed by the direct microscopic count of *individual* cells. As the quality of a given milk supply improves, however, long hours of incubation are involved. This is one of the principal objections to the test.

Because it offers a considerable saving of time over the methylene blue test, the resazurin test has come into the picture in many countries. However, the original "one hour" test as described by Ramsdell and coworkers has certain shortcomings. Milks containing large numbers of dormant bacteria frequently fail to show a significant color change within one hour; the same is true of some herd milks containing large numbers of leucocytes.⁷ If, however, milk is incubated until a pink end point is reached, there is a much better correlation with the methylene blue results with a saving in incubation time of from 25 to 33 per cent.^{2, 7}

While overcoming one shortcoming of the "one hour" test, the "pink" test loses an advantage of the former. Abnormal milk (mastitis, late lactation, colostrum, etc.) shows a distinct color change during the first 2 or 3 hours—though not always in the first hour.⁹

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

† Contribution No. 166 (*Journal Series*) from the Division of Bacteriology and Dairy Research, Science Service, Department of Agriculture, Ottawa, Canada.

Having reached a certain stage, little further change in color takes place until bacterial activity brings about reduction to the pink, and finally to the white stage. Consequently, the pink end point test is of little value in the detection of abnormal herd milks.

In view of the increasing attention being given to abnormal milk in milk control work, a modification of the resazurin test was sought which would combine the sensitivity of the "one hour" test for abnormal milks with the greater accuracy of the "pink end point" test for bacteria. This was finally found in the "triple reading" test described by Johns and Howson,⁹ in which a color approximately half way between the original blue and the full pink (Munsell P 7/4) is taken as the end point. By observing and recording those samples which have passed this end point at 1, 2, and 3 hours, each sample can readily be placed into one of four grades.

The hourly recording of the degree of color change in the resazurin-milk mixture is particularly useful when applied to a reasonably low count milk supply. The lag following the initial marked change indicates those herds where mastitis or stripper cows may be suspected. One Ottawa dairy has made considerable headway in eliminating such abnormal milk through this method.

The triple reading test thus furnishes more complete information concerning the sanitary quality of each producer's milk with less expenditure of time and less need for trained technicians and apparatus than any test we have studied. The saving in time compared with the other dye reduction tests in the evaluation of first grade milks of equivalent quality is evident from the following:

Resazurin triple reading test	3	hours
" pink test	4½	"
Methylene blue (modified)	6	"
" " (standard)	8	"

The resazurin one hour test is useful at the start of a quality control campaign, but since it fails to differentiate between microscopic counts below 2,000,000 per ml.,⁹ a more sensitive test should subsequently be introduced.

Little¹⁰ has adopted a purple pink end point, presumably very close to our Munsell P 7/4. He finds this is reached in approximately half the time required to reduce methylene blue. Fullest information is obtained by observing tubes every ½ hour for 2½ hours, although where this cannot be done milks may be graded by a single reading after 2½ hours. In his latest report¹¹ tubes are read every 30 minutes for 3 hours, when smears are prepared and examined under the microscope to determine the type of bacteria predominating. It may be open to question whether the 30 minute readings he employs yield enough additional information over the hourly readings to warrant their use in a routine test. Burgwald¹ has also found the P 7/4 end point superior to the pink.

One drawback to the wider use of the resazurin test is that many small plants lack facilities for preparing the dye solution. In Britain standardized tablets are now on the market, and no doubt similar tablets will soon be available on this continent.

It should be emphasized that none of the tests ordinarily employed for measuring the bacteriological quality of raw milk can be relied upon to detect large numbers of thermophilic bacteria.¹¹ However, these are less frequently present where the general level of counts is kept low.^{11, 12} Our own studies³ show that of samples showing plate counts of under 5,000 per ml. after laboratory pasteurization, only 12.3 per cent had microscopic clump counts of over 500,000 before pasteurization, while of those over 5,000, 62.7 per cent had counts over 500,000 before pasteurization.

During the past year we have compared various methods suggested for the detection of significant numbers of thermoduric organisms. The resazurin test applied to pasteurized milk was found to be of no value, since thermoduric organisms generally show very weak reducing activity.⁹ In our studies the microscopic count methods described by Hileman and Leber,⁵ and Mallmann, Bryan and Fox¹³ failed to show as good a correlation with the plate count of laboratory pasteurized milk as was reported by the respective authors. The oval tube technic of Myers and Pence¹⁴ gave much better agreement and showed considerable savings in time, media, glassware, and incubator space as compared with the plate method. Little¹¹ also reports very favorably on the oval tube method, and believes it is capable of replacing the plate count altogether in routine control work.

To summarize briefly, a quality control program may be carried out with simplified laboratory procedures which make less demand upon skilled help, apparatus, and supplies. The "triple reading" resazurin test has definite ad-

vantages for the grading of milks on the basis of both bacterial and leucocyte contents, while the oval tube method is preferred following laboratory pasteurization for the detection of milks containing thermoduric organisms in significant numbers.

Laboratory Control of Milk under War Conditions*

The Rapid Phosphatase Test

H. SCHARER, LL.B.

*Chemical Laboratory, Department of Health,
New York, N. Y.*

THE rapid expansion of the use of the phosphatase test in the testing of pasteurized milk supplies almost necessitates a yearly review in order to present the advances in technic and application. Although the test was first presented as an involved laboratory procedure, its simplification has permitted its use by many who would not otherwise be able to avail themselves of its undoubted merit, and accounts for its adoption from Alaska to South Africa, and from Iceland to Australia.

The use of the so-called field test or "screen test" will continue to be justified, particularly in view of the growing shortage of technicians, but its wide adoption, and the increasing reliance placed upon its interpretation, call for a warning note. Almost inevitably, whenever a laboratory procedure is placed at the disposal of persons untrained in the laboratory, there are abuses of technic leading to unreliable results. These abuses usually involve simple precautions which a laboratorian, through his background of training, would always employ. Such conditions involve the careful preparation of reagents and the use of adequate controls. Instructions presented in the "Standard Methods" which were intended to provide safeguards on these

points have not infrequently been glossed over. It is of vital importance that these precautionary safeguards be iterated and reiterated if reliable results are to be obtained, and, conversely, when these simple measures are taken, reliable results are always obtained.

For example, taking into consideration the relative instability of the buffered substrate and the dibromoquinonechloroimide solution, it was urged that fresh solutions should always be employed, and that only sufficient solution be prepared for immediate needs. Bisected tablets were provided which permitted the rapid, inexpensive preparation of solution sufficient for just a few tests, yet there are numerous instances where old solutions are employed, leading to wholly unreliable results which may be either falsely negative or falsely positive, depending on the state of decomposition. If the procedure were adopted of always using known controls of both a pasteurized milk and one to which a small amount of raw milk is added, these false results could immediately be discounted. In the absence of a pasteurized control, it is a relatively simple matter to heat a portion of the sample to above 160° F. for a minute, and then, after permitting it to cool, to use it as a pasteurized control. The so-called positive control, simulating the presence of a small amount of raw milk, can be obtained

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

by adding to this heated sample a small amount of a 0.005 per cent solution of sodium sulfocarbolate (sodium phenolsulfonate).

Unfortunately the manufacture of 2, 6 dibromoquinonechloroimide, is a difficult problem, and it is to be greatly deplored that some of our largest manufacturers have released batches of this compound which are wholly unsuited for use with the phosphatase test. Many users have complained that succeeding batches of this compound, because of its non-uniformity, have given quite different results and even required a new evaluation of standards. One lot of the compound gave a positive on every sample tested. Properly prepared, this compound is available at low cost in the form of golden yellow crystals and is extremely stable and completely reliable.

The use of the double control on the test will also detect those sources of error which are due to the presence of phenolic material in the water used to prepare the disodium phenyl phosphate solution. Where such contamination is indicated, the phenolic product can be removed from the water by extraction with ethyl ether.

The extraction of the indophenol blue, developed in the test by means of neutralized normal butyl alcohol, is a stumbling block for many, since in the desire to prevent the formation of an emulsion, the extraction is frequently incomplete. But if the test tube in which the extraction is performed be inverted quickly, 3 or 4 times, and then laid flat to permit the separation of the butyl alcohol before this act is repeated, the emulsion seldom occurs. Centrifuging, if possible, for .2 or 3 minutes, readily breaks the emulsion and permits evaluation by comparison with the suggested color standards.

The growing strategic importance of normal butyl alcohol to the war effort, and its unavailability to many, have

prompted a further modification of the rapid phosphatase test which is midway between the earlier "field test" and the laboratory procedure, and which can be utilized equally well by the laboratory or the inspector. For that reason, the name "control test" is suggested. A study of the kinetics of the enzyme activity and the inter-related pH conditions of hydrolysis and of the indophenol formation indicated that if the incubation period be extended to 1 hour, and dispensing with the precipitation technic, and adding the dibromoquinonechloroimide directly, the test becomes sufficiently sensitive for all practical purposes, i.e., sufficient color difference is developed between a properly pasteurized milk and an improperly pasteurized sample, to be readily apparent, so that the butyl alcohol technic need only be employed in borderline instances, or where greater certainty is required. This modification is suggested where time is no great factor.

In the application of any of the technics to high temperature-short time pasteurization, it is necessary to have some information regarding the pre-heating time and temperature, as well as the rated holding time and temperature before the results of the test can be properly evaluated. Similarly in the case of cream, it is frequently necessary to have some knowledge of the history, particularly the age of the sample after pasteurization, before a sample may definitely be classed as improperly pasteurized. There are certain bacteria which multiply very rapidly in cream under refrigeration, and which, within 36 to 48 hours after pasteurization, will produce a bacterial phosphatase in quantities sufficient to give a positive test. Moreover, these bacteria are seldom evidenced in the standard plate count, since their optimum growth occurs at temperatures far less than those normally employed. Characteristic of the presence of those organ-

isms, is a peculiarly offensive odor and a thickening of the cream sample. This condition is not met in freshly pasteurized creams. Aside from the exceptions just indicated, and provided acceptable reagents are employed, there

is no reason to doubt a positive finding with the phosphatase test. If inspection fails to indicate the cause, the test results are no less correct and indicate a closer coöperation between inspection and testing.

Laboratory Control of Milk under War Conditions*

Milk Testing, under Emergency Conditions

R. V. STONE, SR., D.V.M., F.A.P.H.A.

Director, Bureau of Public Health Laboratories, Los Angeles County Health Department, Los Angeles, Calif.

THE Pearl Harbor treachery stimulated early action in Los Angeles County to formulate a Dairy Industry Emergency Civilian Defense General Committee. On January 8, 1942, a General Chairman, Acting Secretary, and twelve committees were set up. These included:

- Field Production Committee
- Country Transportation Committee
- Public Utilities Committee
- Emergency Processing Committee
- Blackout, Air Raid, Fire, First Aid, Watchmen and Personnel, Transportation
- Creamery Supply Men Committee
- Bottle Caps and Paper Committee
- Glass Milk Bottles Committee
- Producers Committee
- Rolling Stock Committee
- Labor Committee
- Technical Committee

TECHNICAL COMMITTEE

The Technical Committee was assigned, primarily, to laboratory and associated problems that might be expected as involved in any major bombing or attack disaster. The members of the Technical Committee appointed represent the—

- Los Angeles County Laboratory
- Los Angeles City Laboratory
- Pasadena City Laboratory
- State Department of Agriculture

Dairy Inspection
Dairy Industry

The Dairy Industry Emergency Committee is affiliated with the Los Angeles County Resources and Production Committee, headed by the County Agricultural Commissioner.

The Technical Committee held its first meeting on January 16, 1942.

A free discussion of problems that might be expected as a result of an attempted invasion, etc., was augmented by suggestions received by the chairman of the committee.

Actual problems resulting from invasion or bombing, etc., are anticipated in degrees of minor to major emergencies. Planning effectiveness will only be apparent if and when they must be placed in actual operation.

We have considered possibilities as: (1) Localized damage, minor; major; and (2) County-wide damage, minor; major.

Minor damage would not include serious failures in power or water supplies, but would involve localized or general interference with a normal routine. Major damage would involve the actual paralyzing of the usual accommodations available for standard laboratory procedures.

Within the 4,085 square miles area of Los Angeles County territory, twelve laboratory stations have materials and instruction for proceeding in the case

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

of an emergency. There are sufficient supplies in each center to absorb work from an adjacent damaged area. Previous experiences in a mild earthquake produced inconvenience and provided some guidance in this planning. Personnel are instructed to report as soon as possible to their assigned positions in case of emergency, but if their own station is damaged to such a degree that it is unable to function, then these persons are to report to the next nearest station. Plans are set up for:

1. Conducting the work as nearly by routine procedure as possible.
2. Facilities for emergency procedures are available in each Center.

These include:

1. A stored, stable medium ready to melt and pour into plates.
2. Phosphatase kits (Scharer) sub-strate and indicator tablets.
3. Facilities for microscopy; *E. Coli* index, reductase test, sediment testing, etc., as needed.
4. Facilities for utilizing a substitute for a standard plate count; designed by Ray Hasson of the Griffin-Hasson Laboratories, Los Angeles, Calif.¹ This is a small French square bottle with a Bakelit screw cap; two ounce.

Agar is poured on one inner side of this bottle. The Bakelite cap is screwed on tightly; the bottle neck and cap is then dipped into molten paraffine. This keeps well as a stored, ready to use unit. This can be used even though pipettes, incubators, dilution bottles, etc., are out of commission. Planting is accomplished by pouring the liquid sample onto the surface, and immediately pouring this off, and draining the bottle for a moment before recapping.

Stand on end; cap down during incubation. Colonies developed by this technic compare as favorably to each other, in duplicate, as do standard plate counts. Milk samples can be detected as "too numerous to count," grading down to only one or two or no colonies. Rapid separation of samples into good, fair, poor, and bad is simple, even for an emergency worker, and by visual inspection. Occasional spreaders can give trouble.

A differentiating medium such as E.M.B., can be used in this bottle technic. This is a practical, usable, emergency procedure which requires no laboratory; can be "incubated" at room temperature in a dairy, in a home, almost anywhere, and serves a real emergency need; it should not be "brushed" aside as too far removed from Standard Methods.

Personnel licensed for laboratory practice by the State Department of Public Health is much in demand. In a serious emergency we can anticipate that blood bank and similar activity will necessitate using personnel for some of the work, other than bacteriological major, graduate students. This has been kept in mind in our planning. Procedures that can be carried out by high school or undergraduate student volunteers cannot involve too much skilled technic. The phosphatase, reductase, sediment, and Hasson bottle tests can be satisfactorily assigned to such workers under the supervision of a licensed laboratorian.

Laboratory Control of Milk under War Conditions*

WALTER D. TIEDEMAN, M.C.E., F.A.P.H.A.

Chief, Bureau of Milk Sanitation, State Department of Health, Albany, N. Y.

WAR has brought with it both the usual scarcity of materials and man power affecting all branches of health work, and the possibility of the disruption of normal supplies and procedures by damage from bombing or sabotage.

New York State has made reasonable preparations and taken such precautions as appear to be necessary to minimize the effects of bombing and to frustrate attempts at sabotage.

A matter of immediate concern in milk laboratory work, however, is the shortage of man power and possible shortages of materials such as agar agar that enter into the standard tests usually applied to milk.

This has indicated the necessity for a critical réévaluation of the relative public health values of the various tests being used in the examination of milk. Much has been said in the past^{1, 2, 3} about inaccuracies and inconsistencies in standard plate counts. In recent years some good work has been done to improve the standard plate count technic. However, frequent gross inconsistencies between the standard plate count and direct microscopic count on the same sample of milk indicate that in many instances the standard plate count still comes far from determining the actual bacterial content of the milk.

Furthermore, standard plate counts of samples from a raw milk supply proved to be responsible for an outbreak of septic sore throat showed counts of 10,000 or less with the infected milk in the supply. This is another indication that the standard plate count fails to answer the question that should be uppermost in the health officer's mind, namely, "Is this milk safe for human consumption?"

At the annual meeting of this Association in 1937 Tiedeman and Hohl⁴ advocated the use of the phosphatase test, coliform test, and direct microscopic count instead of the standard plate count in the examination of samples of pasteurized milk. A practical example was cited of a case in which the effort of a health officer to control a pasteurized milk supply using the standard plate count resulted in his unwittingly converting a safe supply of pasteurized milk into a decidedly unsafe one.

There appears to be general agreement among health officials that the public should have milk of good bacteriological or sanitary quality, that has been pasteurized and has not been re-contaminated after pasteurization. Thus the use of the phosphatase test to determine adequate heat treatment or pasteurization, the coliform test to show possible contamination after pasteurization, and the direct microscopic count to indicate bacteria content in a general way should give the health officer just what he needs to know. Of course,

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

the standard plate count may be used in this program, and the proposed use of the direct microscopic count on pasteurized milk requires further explanation.

The phosphatase test for pasteurization has rapidly come into general use. The continuous use of the test in New York State for the past seven years has convinced workers there of its value and reliability. It reveals the thing health officers should want to know most, namely, whether the milk or cream sampled has been adequately heat treated and has not been diluted excessively with raw milk. It appears that the reagents for making this test will continue to be available in wartime. While many man-hours are required to run the test, the work is justified in our opinion until a simpler method of equal reliability is developed, because of the value of the information secured.

The coliform test should be used along with the phosphatase test to detect the possible recontamination of milk or cream after pasteurization, either indirectly or by a very slight dilution with raw milk or cream that cannot be detected by the phosphatase test. This test too requires considerable man power and materials. However, the materials have not as yet become critical and the value of the test in our opinion justifies the expenditure of time.

There is one economy in the use of the coliform test that may be made without much sacrifice. Most laboratories are running three or more tubes. A study of reports on 1,813 coliform tests made in a New York State laboratory shows that the percentage of positive results obtained was increased only from 27.2 to 33.6 per cent by the use of three 1 ml. portions instead of a single 1 ml. portion.

The substitution of the direct microscopic count for the standard plate count in the examination of pasteurized

milk and cream offers the greatest possibility in this field for wartime conservation. Considerable saving is to be made in time and materials. However, although the use of the standard plate count may not be essential, the habit of making and using standard plate counts may be difficult to break.

The question immediately arises whether or not dead bacteria stain and are counted in the direct microscopic method. In using the direct microscopic count on pasteurized milk and cream for plant control during the past five years we have not attempted to settle this issue but have applied the pre-pasteurized bacterial standard to pasteurized milk and cream. The finding of a direct microscopic count above the limit has been interpreted as meaning that the prepasteurized milk did not meet the bacterial limit.

There is evidence^{5, 6} to indicate that dead bacteria, or at least some kinds of dead bacteria, do not stain. However, comparisons of standard plate counts with direct microscopic *clump* counts on identical samples of pasteurized milk show decidedly higher counts by the direct microscopic method. It does not seem to be essential to correlate the two counts, but in our opinion it should be sufficient to set new standards for the direct microscopic clump count on pasteurized milk and cream.

A study of 297 such counts made by Gilcreas will illustrate these variations. Of 240 samples with standard plate counts of 30,000 or less, the following grouping of direct microscopic clump counts were obtained: approximately 43 per cent were 30,000 or less, 22 per cent were more than 30,000 and not over 100,000, 13 per cent were more than 100,000 and not over 200,000, and the remaining 22 per cent were over 200,000.

Investigating the practical aspects of this problem as it applies to 361 comparative counts on samples of pas-

teurized milk, 66.5 per cent of the samples complied with a standard plate count limit of 30,000, and 61.7 per cent of the samples complied with an arbitrary direct microscopic count limit of 200,000. From this it appears that only a slightly lower compliance might be expected with a limit of 200,000 for the direct microscopic clump count on pasteurized milk than with a limit of 30,000 standard plate count.

In our opinion the adoption of a 200,000 direct microscopic clump count limit on pasteurized milk used in conjunction with the phosphatase test and the coliform test should enable health officials to maintain adequate public health control of such milk supplies

without the use of the standard plate count.

Units of Local Health Service for All the States

Progress Report *

BOTH of the professional organizations concerned with the application of the science and art of medicine for the individual and his family, and through the agency of civil government for the protection and promotion of the health of communities and population groups, have within the past year declared in official pronouncements, expressed through the democratic procedure of their representative bodies,[†] their interest in the complete coverage of the area and population of continental United States by local units of health jurisdiction.

Information of a precise and authoritative kind was not available as to the extent to which the services of public health were in fact applied through full-time professionally trained or experienced medical health officers for our people under the jurisdiction of some unit of local government. Nor was there a sound basis of fact from which an estimate could be made of the number of professional and assistant personnel needed to make effective at a

modest or minimal level units of local health service reaching all areas of civil government.

To review the existing full-time local health services in each state and to prepare information in a practical form for use in promoting the extension of such services to their logical completion for all the people, the American Public Health Association, through its standing Committee on Administrative Practice, created in July, 1942, a subcommittee on Local Health Units.

It is assumed that by units of full-time local health service are meant departments of health of single or several counties or districts which are administered by a health officer devoting his entire time to such public employment, with accessory nursing, sanitary, and other personnel in proportion to the population and area involved, and supported by local tax resources or with such appropriations as the community to be served can afford from its own local tax revenue, supplemented by state and federal funds. Neither federal nor state administration of health services, as these are generally accepted, includes primary responsibility for carrying out the local health program, since the major part of direct service to the people can be most efficiently and economically rendered on a community basis.

Neither federal nor state health services can function optimally unless local government accepts primary responsibility for the conduct of those six

* Suggestions for local health units in each state were presented with supporting data in graphic and tabular form at the Annual Meeting of the American Public Health Association in St. Louis, October 26-29, 1942. This progress report was approved by the Committee on Administrative Practice at its meeting in New York, N. Y., December 16-18, 1942.

† Resolution of the House of Delegates of the American Medical Association, June 10, 1942. Published in the *Journal of the American Medical Association*, 119, 10:811 (July 4), 1942. Resolution of the Governing Council of the American Public Health Association, Oct. 29, 1942. Published in the *American Journal of Public Health*, 32, 12:1412 (Dec.), 1942.

standard health activities * which concern directly and in some respects personally the birth, life, sickness, and death of each member of the family and community, and without which the application of preventive medicine through government to any effective degree is impracticable.

In some states the only full-time public health services are those administered and paid for wholly by state government. Wherever such state administrations provide substantially a full-time health service for county or district areas, these are separately listed.

The sources of information upon which the data here presented have been based are (1) for populations and areas of states and counties, the U. S. Bureau of the Census enumeration of April, 1940,† and subsequent Census Bureau estimates of the civil population as of May, 1942 ‡; (2) for the distribution of physicians in active practice and for general hospital beds, the American Medical Association; (3) for the effective buying income by states and counties for 1941, *Sales Management*, issue of April, 1942; and (4) for the location of full-time officers and other similar administrative data, the U. S. Public Health Service and communications from the state health officers.

Analysis of the tabulated material disclosed these significant facts:

- A. In July, 1942, there were 62,032,300 persons (47.1 per cent) in 890 counties in 37 states and the District of Columbia for whom full-time health services were provided by local government in units of one

or more counties or by individual cities within these counties.

- B. There were 16,518,300 (12.5 per cent) other persons in 493 counties in 17 states for whom a full-time health service was provided by state government in single or multiple county units.
- C. In the areas where full-time health service was not provided by either county or state government, there were 77 cities‡ whose aggregate population of 12,066,100 (9.2 per cent) did receive full-time health service through city government.
- D. There were, then, 41,052,600 persons (31.2 per cent) in 1,687 counties in 41 states for whom *no* full-time health service was provided, and 90,616,700 persons (68.8 per cent) in 1,438 counties in 46 states, the District of Columbia, and in 77 cities, for whom full-time health service was provided by a local, city or county, city-county, multi-county, district, or state health department.

Owing to administrative changes due to movement of health officers into the armed forces, and because of considerable and continuing shifts of population within and across state boundaries, these figures must be considered as approximate only at any particular subsequent date.

The following ideas are considered by the committee to be basic and are believed to be acceptable from the points of view of the professions concerned and of the public to be served:

1. No unit of population, large or small, and no square mile of area under our civil government should be without access to or coverage by the services of a professionally trained and experienced health officer, preferably a physician with appropriate associated professional and technical personnel and equipment, and facilities for transportation to all parts of the area of jurisdiction.
2. Local responsibility for the intimate personal protective and preventive services

* Registration, tabulation and analysis of births, deaths and notifiable diseases; Control of Communicable Diseases; Environmental Sanitation; Public Health Laboratory Service; Maternity and Child Hygiene; Public Health Education.

† The total population of the states and the District of Columbia, according to the Census of April, 1940, was 131,669,275. The civil population of the same area estimated by the Census Bureau for May 1, 1942, was 131,315,393.

‡ There were 93 other cities with a combined population of 24,181,600 in 82 counties where the county as well as the city populations were served by full-time health departments. These city and county populations are included among the 62,032,300 and 16,518,300 mentioned in paragraphs A and B above.

for health is a primary essential of a democratic form of government and it should be so specified under state statute. The health functions of local government must be clearly defined, the merit or civil service system must prevail in the selection and continuance in service of the employed personnel, and sources of revenue must be authorized to meet the readily calculable costs of at least a minimal program of local health service.

3. The factors of available professional personnel and of per capita cost of good health services make it appear likely that population units of less than 50,000 may not be able to obtain and support well qualified personnel, and will find it difficult to support a full-time local health unit. For administrative efficiency and economy, a full-time local medical health officer should be employed for population units of not less than approximately 50,000 each. For large units of 250,000 or more, assistant or deputy health officers will be required, often as directors of special activities, as, for control of tuberculosis or venereal diseases, for maternity and child hygiene, malaria control, etc.
4. An area of local health jurisdiction should be of such approximate dimensions that the average distance from the headquarters to the periphery does not exceed 25 to 40 miles.
5. In planning for the creation or development of units of local health jurisdiction, the factors of effective expendable income per capita, the number of persons per physician in active practice in the area and the number of general hospital beds per 1,000 of the population should be taken into consideration. In developing district outlines an endeavor should be made so to group counties or parts of counties as to reduce large inequalities in per capita income by combining urban and rural, high and low income groups in a single jurisdiction where otherwise desirable. Also, in combining counties or parts of counties within one district an attempt should be made to group them so that the ratio of physicians will not be less than 1 to 1,500 of the population and that the general hospital beds available for the community be not less than 3 per 1,000 of the population.
6. The personnel in addition to the medical officer of health believed to be necessary for a good local health service which conducts a modest but balanced program may be expressed by the following minimum ratios:
 - a. One public health nurse for health department purposes to each 5,000 of the population. In each unit of 50,000 population, at least one of the public health nurses should be of supervisory grade.
 - b. Two full-time persons in the field of environmental sanitation for each unit of 50,000 population, one of whom should have professional qualifications in this field, preferably those of a public health or sanitary engineer.
 - c. One clerk for each 15,000 of population.
7. The offices from which local health service is administered should be housed in a permanent construction appropriate to the functions performed and the services rendered.

TABLE 1

Alabama	35	Iowa	36	Nebraska	20	Rhode Island	3
Arizona	7	Kansas	27	Nevada	3	South Carolina	24
Arkansas	29	Kentucky	41	New Hampshire	5	South Dakota	10

Idaho	6	Mississippi	36	Oklahoma	34	West Virginia	15
Illinois	47	Missouri	37	Oregon	14	Wisconsin	20
Indiana	35	Montana	15	Pennsylvania	49	Wyoming	6
						District of Columbia	1

If the principles above expressed so far as size of population and area of units are concerned be accepted, it will be found that approximately 1,127 units of local health jurisdiction will be needed for continental United States, of which 303 would be units of 1 county each, 677 units of 2 to 4 counties, and 147 of more than 4 counties each. It is to be understood that where a city is included within a county, only one unit of local health jurisdiction is to be recommended for both city and county populations.

The suggested numbers of units of local health services for the several states are as shown in Table 1:

Information has been prepared in tabular form giving for each state as a whole and for the suggested units of local health administration, the five items of information above referred to as determining or accessory factors, viz., Area, Population, Effective Expendable Income per Person, Ratio of Population to Practising Physicians, and Ratio of General Hospital Beds per 1,000 Population.

A summary of some of the more important and relevant facts follows.

Among the 48 states, within which there are 3,070 counties, there are 3 with less than 10 counties each (Delaware 3, Rhode Island 5, Connecticut 8), and 8 with 100 or more counties each (North Carolina 100, Illinois 102, Missouri 114, Kentucky 120, Georgia 159, Texas 254, Kansas 105, Virginia 100).

Populations and areas of the counties vary widely from 42 persons to more than 4,000,000, and from 22 square miles to 20,175 in a county. Each state has at least one county with less than 50,000 population and in 7 states the population of each county is less than 50,000, or but slightly more (Idaho, Montana, North Dakota, Nevada, South Dakota, Vermont, and Wyoming).

There are 28 states in which the

largest county has an area of less than 2,000 square miles, that is, with an average radius from a geographic center of about 25 miles.

Among the 3,070 counties and the District of Columbia, there are now approximately 907 administrative health officers in charge of units of local health service under local or state control, serving the populations and areas of 1,383 counties and the District of Columbia. In addition there are 170 full-time city health officers, 93 of whom serve cities which are located in full-time county or multiple county units, and 77 serve cities located in counties with no full-time health service.

The committee offers the suggestion that by combining some counties with others, and by including cities and the counties within which they lie as city-county units for health services, to the end that administrative adequacy and economy be attained in the direction and operation of full-time local health services, a good quality of such service can be obtained for the entire population and area of the United States under 1,127 units of local health jurisdiction under the direction of 1,127 medical officers of health.

There are at present 7 states in which all counties have some form of full-time health service (that is, under local or state direction). These are Alabama, Delaware, Maryland, New Mexico, New York, Utah, and Wisconsin. There are 9 states without full-time health services for any county unit (Connecticut, Maine, Nebraska, Nevada, New Hampshire, New Jersey, Pennsylvania, Rhode Island, and Vermont).

There are 4 states each with 1 county unit of local health administration and no local units under state district health direction (South Dakota, Indiana, Massachusetts, and Wyoming).

The committee does not propose an extension of the single county unit system of local health administration, which

would be administratively and economically unsound for very large areas and sections of the national population and would call for an increase of approximately 2,000 administrative health officers. Nor does it advocate an extension of the state district system of providing local health service, except in such areas and for such sparsely settled portions of some states as make any really effective local or county government impossible, or at least improbable, for a long time to come.

The committee suggests, for the consideration of state health officers and of state medical societies of the respective states, such reorganization and extension of full-time local health service as may be needed to reach all their people and their total area, by applying well established criteria for areas of jurisdiction, for employment of personnel, for the conduct of standard health functions, and for the support of these activities from tax resources.

According to the suggestions of the committee as graphically presented on maps of the respective states, exhibited at the Annual Meeting of the Association in St. Louis in October, 1942, of the 1,127 proposed units in existence or to be developed, 303 would be single county units, 677 units would include 2 to 4 counties, and 147 would be units of more than 4 counties each. In several instances the unit could be best created by including parts of several adjacent counties rather than the entire counties because of the geographical inconveniences in transportation within strictly county lines.

Of the suggested 1,127 units, 117 would have populations somewhat less than 50,000; 749 units would have populations of 50,000 to 100,000; 188 units would be of 100,000 to 250,000; 49 units of 250,000 to 500,000; and 24 would be of more than 500,000 population each.

Of the 1,127 units, 99 would each

have an area of less than 500 square miles; 255 would be units of 500-1,000; 412 of 1,000-2,000; 231 of 2,000-5,000; 76 of 5,000-10,000; and 54 would embrace areas of 10,000 square miles or more.

It would overload this report with figures if the data on expendable income, general hospital beds, and practising physicians by states and by the suggested units of local health jurisdictions were included, although these are available for interested persons through correspondence with the committee.

The committee plans to continue its activities in the following three main directions:

1. Extension of full-time local health service through conference and correspondence with appropriate officers of state government and with representatives of state medical societies and with other interested persons.
2. Analysis of existing statute law, and co-operation with such organizations as the National Conference of Commissioners on Uniform State Laws, to encourage the passage where necessary of enabling legislation permitting or requiring the establishment of local health services as a function of civil government throughout all the states.
3. Study of the quality and number of persons of professional grade needed in full-time employment for the conduct of at least a minimum local health program under the varied conditions of area, population, and economic status of the proposed units of jurisdiction, and preparation of estimates of per capita costs of such services based on experience in existing units. Furthermore, to estimate the number of persons, such as physicians in general and specialty practice, needed in part-time clinic, advisory, and consultative positions in local health units.

The committee hopes to be of service in making practical and effective the spirit and obvious intent of the resolutions adopted by the American Medical Association and by the American Public Health Association.

Local initiative and responsibility for

health protection are believed to be essential for national health in peace and in time of war. In this respect we are now but half prepared as a Nation.

THE COMMISSION ON VITAL RECORDS

A REPORT of the federal government's Commission on Vital Records has just been released. This Commission stems from the Office of Defense Health and Welfare Service. It includes in its membership representatives of the War and Navy Departments, the U. S. Public Health Service, the Bureau of the Census, the Social Security Board, the Office of Civilian Defense, the Department of Justice, the Office of Price Administration, the War Manpower Commission, and state health officers. Dr. Lowell J. Reed, Dean of the Johns Hopkins School of Hygiene and Public Health, is Chairman.

In the development and utilization of vital records in the United States, we have gone through a number of phases, each reflecting a somewhat different approach to the matter. We have now passed well beyond that stage where collection and preservation of such records was a function limited to the church, and have made it a governmental responsibility, usually under health departments. Until recently, the utilization of these records has been largely in terms of their public health significance; only secondarily were they viewed as of evidentiary value in relation to place and date of birth, and parentage of the individual. However, in the past decade, birth certificates have been utilized more than ever before as evidence of these facts and it seems likely that this aspect of the vital records will become increasingly important as the results of social security legislation enter more largely into the life of the average citizen. The war, too, has emphasized the evidentiary value of birth certificates, in that proof of place and date of birth and parentage is demanded in many circumstances. However, heavy demands for certified copies of birth certificates have demonstrated that registration of births has not been nearly so complete as is desirable, that provisions for delayed registration of birth vary markedly in the different states, and that, in industries and even in different agencies of the federal government, there are varying requirements and standards which, when a certified copy of the birth certificate is unobtainable, an individual must meet in establishing age and place

of birth. It is further to be noted that an individual, having established these facts to the satisfaction of one state or governmental agency, has often been no better off as regards the final and permanent establishment of these facts of where and when he was born. Should he later, for instance, shift from employment from one state to another or from one government agency to another, he might find it necessary to obtain a completely new set of affidavits or other substantiating documents and perhaps some not previously required.

The aspects discussed above, of course, constitute only a part of the problems and deficiencies in the forty-eight quite separate state systems for the registration of vital records. These difficulties are recognized by most state health officers and, while there is no desire to replace the state and local systems by a federal one, it has for some time been generally agreed that the federal participation should be more exact, more far-reaching, more focused, and above all should serve as a coordinating element. It was a consciousness of these needs that caused the Conference of State Health Officers to request the Medical and Health Committee of the Defense Health and Welfare Service to appoint the Vital Records Commission, and the judgment of the Commission is reflected in the report under discussion. The Commission reports upon two problems which it considered: (1) The development of a scheme of national registration for purposes of identification of each individual, and (2) the need for a coordinated system of vital records for the United States. As to the first, the Commission reviewed the desirability of and the arguments against national registration in peace and in war, considered the technical difficulties involved, recognized that it would cost no inconsiderable amount and recommended that a national population registration establishing the identity of all people in the United States be carried out at this time if deemed essential to the war effort. The decision as to whether or not such an identification system is essential was beyond the authority of the Commission.

In connection with the second problem, the Commission went no further than to recommend that the existing vital records organizations of the country at national, state, and local levels be strengthened and coordinated into a system. It expressed itself as convinced that a single agency of the federal government should be solely responsible for federal participation in one or both of the undertakings having to do with vital records but it did not recommend which branch of the federal government should be so designated. A further recommendation was that the coordination of the registration systems be effected regardless of whether or not a national registration for identification is put into effect.

The Commission also expressed itself as somewhat concerned over the fact that there exists in the minds of many a confusion as to the functions of *identification*, *verification*, and *certification* as observed in connection with vital records; and believing that clarification is essential to an understanding of the differences between a system of vital records and a national registration system, the Commission in its report undertook to define these terms. It must be confessed, however, that the language in which the definitions are set forth in the report would be improved by a bit of editing. Possibly there were no lawyers present, or perhaps too many. But the report is a social document of unusual value and significance. It represents the distillate of many weary hours of work, of voluminous correspondence, of adjustments and reconciliations of opinions, and of hard thinking. We urge its study by those in public health and we take it upon ourselves to express to the Commission the appreciation of public health workers.

IS THERE AN EPIDEMIC VOMITING DISEASE OF WINTER?

SOME two decades ago alert pediatricians were struck by the fact that from time to time in the winter months they were called upon to attend large numbers of children with unseasonable gastric disturbances. With these experiences, and on a somewhat *post hoc* basis, they became suspicious of milk that had, as it were, frozen on the doorstep. Some felt that, the expansion of freezing having raised the bottle cap, contamination had occurred. Others believed that the milk had undergone a physical change which made it indigestible. Then, in 1929, Zahorsky reported from St. Louis an outbreak which he designated as Hyperemesis Hiemis, or the winter vomiting disease. He stated that he had encountered similar epidemics off and on in the past 30 years, that the outbreaks tended to occur in the winter months. He published another article in 1940 and estimated that in St. Louis, in the period February 2 to February 20 of that year, there had been some three thousand cases of this winter vomiting disease. He did not subscribe to the frozen milk theory but came to the conclusion that the conditions existing in late fall, winter, and occasionally early spring, contributed to an unusual abundance of proteolytic organisms in milk, even though pasteurized; that it was the ingestion of milk heavily loaded with these putrefactive bacteria that caused the vomiting syndrome. In this report there is no evidence that Zahorsky made a detailed epidemiological study of cases as regards the ingestion of the milk in question nor are there any data to substantiate a belief that the disease was in effect limited to those who drank such milk.

A more recent contribution to the literature of the vomiting disease comes from Waring who, in the September, 1942, issue of *The American Journal of Diseases of Children*, reports the vomiting disease as it occurred in Charleston, S. C., in the winters of 1941 and 1942. He estimates that the number of cases was in the thousands, with symptomatology essentially the same as reported by Zahorsky. In addition, many other outbreaks have occurred, some of which have been studied, but the majority were uninvestigated and unreported. Waring's observations would tend to offset Zahorsky's hypothesis that the causative factor is milk with a high content of putrefactive organisms, in that there appears to be no food or drink common to the Charleston cases.

The condition seems to be limited essentially to young children, although occasionally adults are affected. When there are multiple cases in a family, the outbreak is not explosive, as in food poisoning, but the individual cases tend to occur in sequence: One child has an abrupt onset, is ill for two or three days, then a second child is affected and possibly a third individual some days later. This causes one to speculate as to a period of incubation. High fever is not a characteristic, though usually there is a slight elevation of temperature. Zahorsky reported more than half of the cases to have a coincident upper respiratory infection. Waring found respiratory involvement unusual. The stools are loose, light in color, without pus or blood, with an offensive odor suggestive of putrefaction. The most characteristic symptom, however, is vomiting. In many instances this is violent, frequent, and excited by anything taken into the stomach. The disturbance lasts for from two to four days and, though the child sometimes appears quite ill and may give evidence of dehydration and rather serious exhaustion, fatalities are practically unknown.

In the outbreaks reported, it has seemed not practicable to obtain productive bacteriological and virus studies, nor have the conditions been such as to permit the

collection of detailed epidemiological data. More information is therefore needed before it may be concluded that one and only one cause is operative, that one and only one condition is being dealt with, that this one cause will produce only this one condition, and that this condition may be produced only by this one cause, etc. It may all be a mare's nest, sheer coincidence, a syndrome brought about by diverse causes, the by-product of a sore throat or, possibly that rock of refuge, "intestinal flu."

Epidemiologists who feel that there is little left for investigation might do well to keep alert as to the occurrence of the winter vomiting disease in their communities. Here is a chance to assist in obtaining an answer as to whether or not this is a clinical entity. If it is, is it infectious and how; and what is the nature of the infectious agent?

LETTER TO THE EDITOR

TO THE EDITOR:

For some time now, I have cherished the opinion that the JOURNAL does not make statistical mistakes or indulge in bad statistical practice. I should like to comment, therefore, on a minuscule item on page 94 of the current January number, Vol. 33, Number 1. Under the heading "Epidemiologic Note" you quote an average incubation period of "12.2 plus or minus 1.1 days."

It is our practice to teach that the use of the \pm following an average is distinctly undesirable, especially where it is not clear from the context what the number following the \pm stands for. That number is usually the probable error of the average in question, although there are instances where it turned out to be the standard error. In either instance, I venture to say, the meaning of the \pm term is not clear to the average reader, and for that reason it had best be avoided.

Referring to the article you cite in the J.A.M.A., and without attempting to reconstruct the calculations based on the data presented, it may be assumed that the average of 12.2 days has a probable error of 1.1 days. Strictly this should be interpreted to mean that if the true average incubation period for all cases were 12.2 days, and if sets of

observations similar to those presented could be made repeatedly, the averages could be expected to vary due to chance alone so that only 50 per cent of them would lie between 12.2—1.1, or 11.1 days, and 12.2+1.1, or 13.3 days. The remaining 50 per cent of the averages would be expected to lie outside of this range, i.e., below 11.1 days or above 13.3 days. Moreover, it is not known that the true average is 12.2 days, and by reasoning from the above it could easily be as low as 8.9 days or as high as 15.5 days (three probable errors below or above the observed average), assuming a normal distribution of incubation periods. In other words, if the true average were 8.9 days, the average of 12.2 days observed here could easily have occurred due to chance variation alone. Similarly if the true average were 15.5 days.

In a group of 37 cases therefore, one should not be surprised to find an average anywhere from three probable errors below the lowest likely true average to three probable errors above the highest likely true average, namely, between 5.6 days and 18.8 days. Unfortunately, very few readers would instinctively place this interpretation on the expression "an average of 12.2 \pm 1.1 days." I believe it is safe to say that most per-

sons would simply conclude that the average may vary from 11.1 to 13.3, and no more, which would be incorrect.

In order to avoid misleading the uninitiated, I believe one should merely state that an average of 12.2 days was observed, and that this average had a standard error of 1.6 days (the figure from which a probable error of 1.1 days must have been derived). A careful reader would then make it his business to understand the meaning of "standard error." The use of the notation " \pm " followed by the value of one probable error does not convey the thoughts of

modern statistical reasoning. It should be considered as out-of-date as the idea of keeping our screened windows shut tight at night in order to avoid malaria. I should like to suggest that the JOURNAL promote the education of the average reader in this respect as it does in so many other respects.

Report of the Chairman of the Executive Board to the Governing Council*

TWELVE days after Pearl Harbor, the American Public Health Association, through its Executive Board, made a declaration for the fourth time since its foundation in 1872 of its professional aims in the interest of national health. The declaration had behind it the urgency of the days immediately following December 7, when every American took counsel with himself and asked "What can I do?"

It seemed imperative to remind public health workers that they might show the highest standard of practical patriotism by staying on their jobs. It seemed imperative, too, to state in terms of the present, because of their vastly heightened need, certain long-term objectives with respect to official health organization in the United States. This was intended to suggest a wartime platform for the public health profession.

The Declaration read in part:

"While health officers and health departments, state and local, city and rural, are expected always to be on duty to fulfil urgent and enduring needs of every population unit and area under the jurisdiction of civil government, the state of war calls for a clarification of aims, some simplification of organization, and a considerable strengthening of effort to develop and keep fit a nation of superior men, women, and children, capable of an optimum life within the privileges and duties of free peoples. . . .

"Our one first aim is victory for the United Nations, and to this end, we, as a body of public servants, pledge all the resources of our professional and technical capacities.

"Any neglect or curtailment of the essential protection of civilian health, whether at home or in the factory or other work place, is inconsistent with maximum efficiency of the military forces.

"The trained civil health worker is properly considered indispensable to the maintenance of national health, and he should be encouraged to continue at his regular station in civil government unless it becomes perfectly clear that the war can be more effectively prosecuted by his transfer to military service.

"Those states and more limited areas now wholly or in large measure lacking the reality and, in some instances, even the form of responsible health service by trained and experienced health officers, devoting their entire time to the public need, and to enforcing the reasonable and necessary provisions of sanitary and public health law, should with all speed be provided with health officers competent to give leadership and direction, and authorized to spend public funds sufficient to make health services a reality for every unit of population and for every area of civil jurisdiction.

"The effective modern health department, as now conceived and at present organized in many states, cities, and counties as a branch of civil government, comprises a medical, sanitary, and related biological and social competence which enjoys broad authority to meet a wide variety of medical and environmental emergencies.

"Where such an organization exists and has under control the preventable factors related to disease and death, the health officer and his staff must be alert to extend, and, if necessary, to modify the usually accepted health functions to meet the multitude of exceptional situations certain to be created by the state of war and by the mobilization of all the people and their industry to support the armed forces.

"In spite of the fact that the creation of authority and organization of health resources of the respective states and insular and territorial jurisdictions on a centralized basis under the federal government appears at present to be neither desirable politically nor

* Presented at the Seventy-first Annual Meeting of the American Public Health Association in St. Louis, Mo., October 26, 1942.

practical legally, nevertheless, the American Public Health Association recommends and urges upon the health officers of every jurisdiction of civil government in the United States, that they think of themselves as conducting an essential portion of a national project for the people's health and acting at all times as if they were in fact and within the law at the administrative disposition of the Surgeon General of the United States Public Health Service.

"If we will accept and act with vision and confidence upon the principles and policies here declared, it will appear that what is needed for victory in arms will be provided for both military and civil portions of our population without sacrifice of the continuing and progressive health needs of a people devoted to the humanities of peace."*

Twelve days after Pearl Harbor, the Executive Board devoted many hours to a discussion of the obligations and responsibilities of the American Public Health Association, as the recognized organization of the public health profession in the national crisis. The conclusion was finally reached that the Association would more appropriately carry on its routines, responding to calls upon it as occasions might demand, than to set up a predetermined plan of immediate and future action.

It was the conviction of the Board that, as mobility and maneuverability are very valuable characteristics of our war machines, so are they in a professional society working in a sphere where there are as many variables as exist in public health. The Board saw its duty as that of keeping our professional society in a position to swing into action on demand, and to be ready, at a moment's notice, to direct our professional strength against any salient that might be assigned to us.

This decision, too, is found to have been wise.

The pattern of the Association's work during this wartime year has been adjusted to these decisions of the Execu-

tive Board. We have moved to closer and closer identification with the war. Documentation will be found on every page of the program of this 71st Annual Meeting and throughout the agenda for the meetings of the Governing Council.

As Americans and as public health workers we have witnessed and have been affected by the national readjustment from pursuits of peacetime to armed conflict. No aspect of the transformation has been without special significance for the public health worker. Think for a moment of a few of the new words and phrases which are in general use, and consider the public health worker's concept of them and that of the general public. "Defense area" and "critical area" awaken his professional instincts, conveying to him more than the fact that business is booming. "Rationing" of food, of fuel, and of some critical materials means shortages and inconveniences to the public but, to the health worker, they mean possible health hazards. Rehearsals of procedures to be followed in case of "air-raids" are coming to be common practice. No one better than the health officer realizes how much more than the rescue and treatment of "casualties" would be involved in the bombing of a community. The phenomenal "defense plant" wages made possible by long work hours are not cause for jubilation to the health worker, nor are the lowering of standards for working conditions and for occupational age levels. His problems increase with the building of the new airplane factory on the edge of town, although it brings a seeming prosperity to the townspeople. Plans for "evacuation" of populations, or of mothers and children, are being worked out in many places, with frequently unacknowledged, but ultimately great dependence upon the health personnel of the areas. And, while the nation has been absorbing the full fact of war, while the new situations with all their

* A.P.H.A. Yearbook, 1941-1942 (Supp. to A.J.P.H., Mar., 1942, p. 40.

important implications for health workers have been expanding our vocabularies, our trained public health workers, never ideally numerous in ordinary times, have been and are being increasingly drawn for service in the armed forces. These facts have not been outside the focus of Association interest.

It is inevitable that the awareness of public health workers to these problems and their attempts to cope with them should be the very fabric of the 1942 meeting of the Association. What will be said will encourage, or some of it may depress us, but certain it is that we start forces in motion here, for better or worse, which will not be spent for months and years to come.

Recognition of the authority of the Association has come from many sources this year. The Army and the Navy have purchased hundreds of copies of *Standard Methods for the Examination of Water and Sewage*, and *Standard Methods for the Examination of Dairy Products*. The volume on *Diagnostic Procedures and Reagents*, among other Association publications, has been micro-filmed and flown to China for use in war areas. A condensed version, in Spanish, of *Standard Methods for the Examination of Dairy Products* is under discussion as a result of frequently expressed need by health workers in Latin American countries. The American Red Cross has designated the *Report of the Committee on the Control of Communicable Diseases* as an essential item in the equipment of its instructors in first aid. Another interesting fact about this report is that its placement in the hands of all the state health officers early this spring resulted in not a few revisions of communicable disease regulations and a wide distribution of the report which has been reprinted by the United States Government. The Tolan Committee on Defense Migration of the Congress called representatives of the Association to testify before it. The U.

S. Public Health Service published, as *Reprint 2359* from *Public Health Reports*, an appraisal technic for urban problem areas as a basis for housing policy of local governments, a report of a subcommittee of our Committee on the Hygiene of Housing. One need only scan the numerous published summaries of happenings in public health and related professions, and examine bibliographies supporting articles appearing in books and periodicals which serve many varied fields, to see how heavily the authors have leaned on the JOURNAL and other Association publications. These examples are a very few of many that might be cited.

We have said that progress can be reported toward putting into effect certain recommendations in our latest official declaration of policy. One of these was "clarification of aims." The JOURNAL may be credited with accomplishing some of that. Responsible for the wise selection of articles and the interpretive editorials are Dr. Harry S. Mustard, the Editor, an office he has distinguished for nearly two years, and a group of associate editors which was enlarged during the year to bring even more special skills into publication counsels. "Some simplification of organization" was another recommendation. A recently appointed and very active Subcommittee on Local Health Units of the Committee on Administrative Practice, under the Chairmanship of Dr. Haven Emerson, is now at work with this end in view. It is studying the present status of locally governed health units in the United States and will propose a redistribution of area and population, under full-time health units, which will be consistent with good administrative practice. The first report of the committee * will be made at this meeting in the form of an exhibit of state

* See report, page 404, this issue.

maps, showing present areas of local health administration and proposals for health units under full-time medical health officers. Although these suggested groupings of area and population are of a tentative and provisional nature, they serve better than any previous attempt as a basis for discussion of the number of doctors, engineers, nurses, and other specialists which will be required in any adequate health program for the nation and, as well, the number of persons of such training which should be withheld, for national safety, from military service. It is gratifying to note the common interest in this field of investigation between the American Public Health Association and the American Medical Association. The House of Delegates of the latter organization has recently passed a resolution signifying its belief in the need for, and its intention toward implementing, such a study as our committee has now undertaken.

A third recommendation was "a strengthening of effort." This is a matter for the individual health worker, for committees and sections in his professional society, and for the society itself, where individuals, committees and sections are extended, and where interplay and teamwork of the whole are made possible. We shall have evidence at this meeting of how much strengthening of effort has been achieved.

As for our routines, and they are described thus only to differentiate them from activities begun or strikingly altered during the year upon which we are reporting, they go on—showing constant growth and development as they have for several years past. I refer to the promotion and maintenance of membership, the Employment Service, the Information Service, the Book Service, and other projects which render service to the membership or which add to our revenues in order that the membership may be better served. We have announced in successive reports member-

ship figures that exceed those of the year before. We have pleasure in doing it again. The number of members and Fellows on the rolls on the first of September, 1941, was 7,108; on the first of September, 1942, it was 7,489, again an all time high.

The attention of the Governing Council was drawn last year to the extraordinarily high qualifications among many of the applicants for Fellowship whose names were presented for Council action. We said that this augured well for Association leadership. It is possible to speak with equal pride of the 139 Fellowship applicants whose names will come before you this year. It is a testimony to the growing prestige of the Association that 468 persons have asked and received this recognition at the last five annual sessions. The higher standards imposed by the Governing Council during this period have resulted in more than doubling the number of applicants.

Several new Association publications have appeared during 1942, among them the first section of an extensive report on lead poisoning, by a committee of the Industrial Hygiene Section, and a report on bathing places by the Joint Committee of the Conference of State Sanitary Engineers and our Engineering Section. *Community Organization for Health Education*, a report of a study of a committee of the same name, made possible by a grant from the Charles H. Hood Educational Trust, was widely accepted, and the entire edition of 10,000 copies was distributed. The Committee on Professional Education has issued additional reports on educational qualifications of several categories of public health workers.

The Association during the year has been actively identified in the developing program of the National Health Council and its Committee for the Study of Voluntary Health Agencies. An appropriation for this purpose over a three year period has been made by the

Rockefeller Foundation, and Selskar M. Gunn, Vice-President of the Rockefeller Foundation, has been given leave to direct this study. Association channels have been useful in the early months of this work to promote an understanding among health workers as to the purposes of the study and to open doors locally for Mr. Gunn and his associate Philip Platt, Ph.D., recently of Honolulu. The work of this committee will be the subject of a general session at this meeting. It is to be hoped that out of the study there may come a new orientation of voluntary agencies in the American scene.

In connection with the current widespread desire to promote hemispheric relations among the republics in this part of the world, it is interesting to recall that 1942 marks the 40th anniversary of the formal identification of the Republic of Cuba with the American Public Health Association, and, as well, the 50th anniversary of the extension to Mexico of the Association's sphere of influence. This is no new program for the American Public Health Association. It will be recalled that, at the 70th Annual Meeting in Atlantic City, no less than 44 representatives were present from Latin American countries, thanks to the coöperation of the Pan American Sanitary Bureau and the Coördinator of Inter American Affairs. It was a fine opportunity to build strong bridges of understanding in the applied science of public health. It is hoped that the invitations extended to these countries again to be represented at this meeting may be accepted. The Chairman of the Executive Board had the opportunity in person to present recently at the meeting of the Pan American Sanitary Conference in Rio an invitation to his colleagues, with special reference to the public health engineers, among whom there is increasing evidence of the shift of their interest to North America.

It is worthy of note that the official agencies responsible for the organized effort of promoting understanding between the republics of the Western Hemisphere have adopted projects in public health as an opportunity to express the growing interest and the co-operative support for this part of our common destiny. Well qualified leaders among those identified with the American Public Health Association are responsible for the health aspects of this program. If any further evidence were needed of the acceptability of public health as a means of promoting national and international welfare, this adoption by official agencies of the technics long used by this professional society and by the foundations is outstanding.

There is currently under discussion the desirability of preparing an abbreviated document summarizing the steps in the laboratory examination of milk as outlined in the 8th edition of *Standard Methods for the Examination of Dairy Products* and for the translation of this digest into Spanish, in order that the technical staffs as well as the directors of these laboratories in Spanish-speaking countries may have access to this American Public Health Association standard with its increasing international significance.

It is not the purpose of this report on behalf of the Executive Board to encroach upon the special fields of interest of the standing committees, on which there will be formal reports by the respective chairman. Mention must be made, however, because of its significance from the standpoint of Association policy, of the present status of the Merit System project. Begun more than a year ago on a modest basis, this effort to prepare examination questions for workers in the various public health specialties has expanded until it is now possible to estimate something of the scope and importance of the venture.

Originally started at the request of

the U. S. Children's Bureau and the U. S. Public Health Service, this venture grew out of a recognition of the lack of competent materials for the examination of professional workers in public health. In an effort to apply what is good practice in personnel administration and examination technic, a study was begun and questions were developed in the field of public health nursing.

Through the generosity of the Children's Bureau, which loaned a staff member, and with the coöperation of several state health officers, funds were made available for this study and a staff was employed which has now developed questions for public health nursing of the objective type to the number of more than 2,000. These have been made available to several state merit system councils on request and are accessible to all such agencies on a non-profit basis.

The success of the nursing questions has been such that the project has now moved into the field of preparing material for the examination of administrative health officers, and we hope soon to explore the field of environmental sanitation and the field of the laboratory. It is necessary for this purpose to maintain a staff of test technicians and subject matter specialists, and continually to secure the counsel of young and imaginative workers of the better sort.

Assured of splendid coöperation from the members of the public health profession, this project can be expected to move into new ground and to continue to realize the expectations which the Committee on Professional Education, the Executive Board, and the Governing Council have hitherto expressed, believing that this is one of the most productive and fruitful enterprises with long-range relationships to the quality of public health work which the Association in its long history has ever sponsored. Opportunities will be afforded at this Annual Meeting to extend the

understanding by public health workers of this venture.

FINANCIAL STATUS

The financial status of the Association again gives cause for satisfaction. The year ending December 31, 1941, was closed with a small surplus, and for the first nine months of the current year both estimates of expense and income have kept approximately within the budget adopted by the Executive Board in December, 1941, which anticipated total expenditures for the year of \$162,212.35, and total income of \$162,386.67. Increases in the expense of JOURNAL publication due to printing and paper costs represent the only substantial deviation from these estimates. An increased circulation has put an even greater strain on these items in the budget but it is expected that the overall balance will be not unfavorable. It is reasonable to expect, we think, that these estimates will stand until the Executive Board is able to review the experience of eleven months when it meets in December, and in particular, to know the result of this Annual Meeting which is the largest variable item in the budget and about which we must make our estimates conservatively.

ACKNOWLEDGMENTS

Once more it is my pleasure to congratulate all who have given service in this coöperative enterprise which is the American Public Health Association—the members of the Governing Council, of the Executive Board, the officers and sectional committees, the standing committees, or those who have helped in some other capacity to make this 70th year important in Association annals. We bring sincere thanks to those individuals and agencies who have provided funds for Association purposes without which a good deal of our work could not have been done this year—or

any year. The following list of sustaining members of the Association represents, in the aggregate, an item which is 11 per cent of our membership income, and which has helped beyond any other single category of the membership to sustain the Association through lean years and to provide a backlog at all times that has made possible many of the objective achievements of this professional society:

The Chlorine Institute, 30 E. 42nd Street, New York, N. Y.
 Mrs. Moses H. Cone, 1800 Eutaw Place, Baltimore, Md.
 Equitable Life Assurance Society, 393 Seventh Avenue, New York, N. Y.
 The Gilliland Laboratories, Marietta, Pa.
 International Association of Ice Cream Manufacturers, 1105 Barr Building, Washington, D. C.
 John Hancock Mutual Life Insurance Company, Boston, Mass.
 Life Insurance Company of Virginia, Richmond, Va.
 Metropolitan Life Insurance Company, New York, N. Y.
 National Life Insurance Company, Montpelier, Vt.
 The Prudential Insurance Company of America, Newark, N. J.
 Sun Life Insurance Company of America, Baltimore, Md.
 The Travelers Insurance Company, Hartford, Conn.
 Union Central Life Insurance Company, Cincinnati, Ohio
 Western and Southern Life Insurance Company, Cincinnati, Ohio

To our advertisers and our commercial exhibitors, many of whom are long-time and faithful friends, we express our appreciation for continued interest and support.

In addition, I wish to thank the W. K. Kellogg Foundation, the Commonwealth Fund, the Metropolitan Insurance Company, the Milbank Memorial Fund, and the John B. Pierce Foundation for contributions which have made possible the rural and city health conservation contests, the work of the Committee on State Studies, the work of the Committee on the Hygiene of Housing, and other activities to which reference is elsewhere made.

The large amount of work accomplished by the Association during this past year reflects the earnestness, enthusiasm, and hard work of Dr. Reginald M. Atwater, the Executive Secretary, and his staff of loyal workers. The Association is deeply grateful to this group which has served so quietly, smoothly, and effectively.

So, in brief summary, stands the 70th year of the American Public Health Association. To the record there should be added the twelve issues of the *American Journal of Public Health*, the 1941-1942 *Year Book*, the 20th edition of the *Bibliography on Public Health and Allied Subjects*, *News Letters*, *Proceedings of the Eighth Institute on Health Education*, and other periodical publications of the Association. Even then one must admit that the most vital contributions of this society lie in an intangible realm, where the growth of our leadership and prestige is to be found. It is a good record to mark this anniversary year of the Association.

ABEL WOLMAN, DR.ENG., *Chairman*

Administrative Practice*

THE Committee on Administrative Practice acknowledges with gratification the leadership of Dr. Eugene L. Bishop who served as its Chairman from 1937 through 1941. The record of the committee's activities during this period is a splendid tribute to his far-sighted guidance.

During the past twelve months, the program of the Committee on Administrative Practice, which begins its 23rd year at the 71st Annual Meeting of the American Public Health Association, has been divided into three categories:

1. Conduct of Special Studies and Services
2. The Analysis and Evaluation of Administrative Practices
3. State Studies and Consultation Service

SPECIAL STUDIES AND SERVICES

The interest of industrial and trade organizations in industrial hygiene and the activities that are being sponsored in this field have been fostered, in no small measure, through the interest and activities of the Subcommittee on Industrial Health Studies during the past several years. This group has attempted to publicize the value of applying the health appraisal plan to industry.

At the December meeting of the Committee on Administrative Practice in New York, this subcommittee felt that its original purposes had been fulfilled, and suggested the possible desirability of its discharge. The Committee on Administrative Practice, however, believed that it was essential for the Association to promote activities in the field of industrial hygiene during the

national emergency period and in the post-emergency period. It was therefore decided that this subcommittee would be continued and that its personnel be augmented or reorganized and its program broadened as the situation warrants.

The Subcommittee on Public Health Nursing which functions as the Committee on Nursing Administration of the National Organization for Public Health Nursing has proceeded with a study of nursing services in clinics. The field work for this study has been supplied by consultants of the U. S. Public Health Service and the Children's Bureau. Information based on a special schedule has been collected and is in the process of tabulation for approximately 200 types of clinics in various parts of the country.

It is anticipated that a report on this study will be released by the end of the year. This subcommittee proposes to make public this information as soon as possible since it is believed that it will be of assistance to agencies faced with making administrative changes due to the war effort.

The Study Committee, of the Subcommittee on State Health Studies, which has been concerned with the Development of Principles and Criteria for the Allocation of Public Health Funds from the State to the Municipal and Rural Health Units has held its activities in abeyance in the past several months on the recommendation of the chairman.

The Subcommittee on Manual of Practice and Appraisal of Local Health Work is collecting information for the revision of the *Appraisal Form for Local Health Work*, but it will in all

* Report of the Chairman of the Committee to the Governing Council, October 26, 1942.

probability not publish the final revision until the war is over.

The Study Committee on Sanitation has now completed a *Special Sanitation Appraisal Form for Local Health Work*, and the preliminary trial of this form has been approved when and if funds can be secured which will make this possible.

A new Subcommittee on Local Health Units was recently appointed to attempt to determine how many health officers were actually needed for local health jurisdiction on a full-time basis in order to render adequate service for all areas of the country. It was felt that until such an analysis was made there would be no way in which to determine how many physicians and other personnel with special health training should be held out of military service, if possible, in order to insure reasonable health services for the country as a whole.

ANALYSIS AND EVALUATION OF ADMINISTRATIVE PRACTICES

The Measles Studies have been continued and a report on these was presented at a meeting of this Subcommittee on Evaluations held during the Annual Meeting. Tests of specific pertussis antigen for skin reactions have been made during the past year and were also reported on at the meeting of the subcommittee just referred to.

The Goiter Study Committee has carried on active conferences and study work and has been attempting to prepare a report on which a statesmanlike and effective national program for goiter prevention can be based. The report of this committee was also discussed at the meeting.

A report of the five year studies on diphtheria was published in the July, 1942, issue of the *American Journal of Public Health*.

Another evaluation study which is being conducted on a limited scale is that promoted by the Subcommittee on

Organized Care of the Sick. This group has been largely concerned with the problem of public medical services as exemplified by the provision of medical care to recipients of public assistance and to the medically needy. A brief questionnaire on the administration of general medical services by health departments has also been prepared, and information is being secured by the Field Staff of the American Public Health Association during their regular field trips. It is hoped that in due time sufficient information will be available to permit a careful analysis.

The annual City and Rural Health Contests, recently renamed the "National Health Honor Roll," were announced in June. The *Fact-finding Schedule* has been further revised and is now known as the "Evaluation Schedule." Last year's revision demonstrated the value of the new schedule as a stimulating tool for the progressive health officer. Now refinements have been made as a result of one year's experience.

The need of good citizen health in wartime has stimulated activity in the National Health Honor Roll and the enrollment records to date are as follows: There are 150 individual cities and 350 counties enrolled, each of the latter has at least one city in its area. Therefore, including only the county seat in the participating counties the total number of entries is 500 cities and 350 counties.

A four page miniature newspaper devoted entirely to the Health Contests—now the National Health Honor Roll—is issued monthly, and the health officers have been very coöperative in preparing material for it. The value of this little paper as a means of exchanging ideas and telling of results of participation has been amazing. In order further to stimulate interest, those cities and counties which attained the National Health Honor Roll last year

will be carried on the Honor Roll for at least two years without the necessity of filling out the complete *Evaluation Schedule*, provided they satisfy the Grading Committee that their programs have not retrogressed.

STATE STUDIES AND CONSULTATION SERVICE

During the past year, under the sponsorship of the Subcommittee on State Health Administration, the States of Illinois and Washington were studied. A request for a survey of West Virginia was also accepted by the Subcommittee, and preliminary work was started in the state but because of a serious depletion of professional personnel in the State Health Department, it was finally decided not to continue the study at this time. This decision was accepted by the State Department of Health, and the West Virginia Public Health Association as well as by the Subcommittee on State Health Administration.

In addition to the two new states studies, continued advisory service was given to Oklahoma, Florida, and Manitoba. Considerable service was also given in Michigan, but since this was financed by the W. K. Kellogg Foundation it cannot be considered consultation service in behalf of state studies, but it is hoped that the work may have a beneficial effect upon public health practice in that state.

A highlight of the state studies project during this year was the governmental meeting called by the Premier of Manitoba shortly after the report of that study had reached the members of Parliament. The field director of the American Public Health Association was invited, and a discussion of the recommendations of the study lasted over four hours. This meeting resulted in effective action.

The provincial legislature increased its public health appropriations by over \$60,000 (a substantial amount in Manitoba) to carry out the more important major recommendations.

A study of "Public Health in the Oranges and Maplewood, New Jersey" was made with the coöperation of the National Organization for Public Health Nursing, at the request of Community Chests and Councils, Inc.

Under the auspices of the Committee on Administrative Practice, at the request of Community Chests and Councils, Inc., and the Columbus Community Chest, Professor Ira V. Hiscock completed a public health study in Columbus and Franklin County, Ohio, which has already produced gratifying results.

In summarizing the activities of the Committee on Administrative Practice during the past year, it is apparent that every effort has been made to promote and carry on its program in such a way as to make available all the resources of its facilities to the war effort. The Information Service which it conducts for the Association has been able to assist various branches of the army and navy in securing certain types of information. The entire program of the committee, although it has not been set up on a wartime basis, has been sufficiently flexible to embrace whatever activities, within its scope, might be of general use at this critical time.

The greetings of the committee are extended to its many friends. Its appreciation for the assistance of those who have helped in its promotion in the past year is best expressed in its resolve to expand its program further in whatever way will be of most assistance in the promotion of public health.

HENRY F. VAUGHAN, DR.P.H.,
Chairman

Professional Education*

ON October 25, 1932, ten years ago yesterday, the Governing Council approved an amendment to the By-Laws which resulted in the birth of a new standing committee to be known as the Committee on Professional Education. Today, as we celebrate the tenth anniversary of this committee we rededicate ourselves to the task of "carrying out research and the development of standards for professional education and training in public health . . . with a view to maintaining professional qualifications of high standard"—a charge bestowed on us at our birth.

While we are aware of our infancy in the family of the Association's standing committees, we believe there is justification for our pride in the accomplishments which the years have produced. I refer to the formal reports which have received the blessing and approval of this Council. Much effort has gone into the making of these reports, and at times it has seemed as though the obstacles were insurmountable. It is a tribute to the men and women who have served their Association so well as members of this committee and its subcommittees that the general acceptance of these reports has become an established fact. Many of you will recall the controversy that raged around the Report on the Educational Qualifications of Health Officers. Today it stands as an accepted document by the profession. Similarly, the reports dealing with educational qualifications of public health engineers, sanitarians, subprofessional field personnel in sanitation, statisticians, nutritionists in health agencies, school health educators, and industrial

hygienists, emerged from controversy as sound contributions to "professional qualifications of high standard."

Lest it be thought that in our satisfaction at these accomplishments we are content to accept your approval of a report as carrying with it a stamp of finality, I mention again our established policy of reviewing these statements from time to time and revising them as the need arises. As evidence of this intent we shall ask you today to withdraw a report which you approved in 1938, because we are convinced that it has already served its usefulness and the changes brought by time have made it desirable that a new report be drawn up. We shall also ask your approval of a revised report on "Recommended Qualifications for Public Health Nursing Personnel."

Even though the members of this committee are so widely scattered geographically that it is not possible to hold more than one interim meeting between Annual Meetings, it is always a source of satisfaction to note the large attendance at these sessions and the inherent interest in the committee's affairs by its membership. It is particularly gratifying to note the deep interest of several members of the Executive Board whose attendance at these meetings has become more and more frequent.

When last we met in April, a careful review and evaluation of our procedures was made. Your committee faced realistically the fact that there will be a tendency to lower educational qualifications because of the current shortage of professional personnel. With confidence in the future, however, the committee expressed its belief that it should continue to aim at high standards rather than risk the effects of incompetence if

* Report of the Chairman of the Committee to the Governing Council, October 26, 1942.

standards were lowered. We recognize the fact that temporary expedients may have to be resorted to by some health departments during the early war period.

On the theory that all those who choose public health as a career should have basic training in public health, the committee agreed on the principle that, for the time being, professional education should be considered to mean public health training at the graduate level, or subsequent to basic or legally recognized professional training.

A uniform outline for the preparation of all future reports has been adopted, as well as a routine of procedure for dealing with subcommittee reports. These, we believe, will provide the Council with mature reports reflecting the maximum agreement obtainable among all interested parties.

A most significant statement was issued by this group as a memorandum entitled "Minimum Educational Facilities Necessary for the Postgraduate Education of Those Seeking Careers in Public Health." This statement was published in the JOURNAL* and was sent to the dean of every medical college, to all schools of public health, to university presidents, as well as to other influential groups. We believe this document has important bearing on the situation which we face today in the education of those who will be the professional leaders of tomorrow.

We feel that this statement is sound for the time being, and that it is of considerable current importance to those contemplating the establishment of schools of public health, as well as those seeking good public health training.

Pursuing its policy of coöperation with other groups, the committee has worked closely with the Committee on Teaching of Public Health and Preventive Medicine of the Association of

American Medical Colleges. This latter group in April brought to your committee a report which covered findings and conclusions as to the present status of teaching preventive medicine and public health to medical students. It is hoped eventually that the committees involved in these Associations may reach certain definite principles and approach a report that can be submitted to and approved by both associations. At the session of the Committee on Professional Education, Dr. Wilson G. Smillie, *Chairman* of our Subcommittee on Teaching Preventive Medicine to Undergraduate Medical Students, will report on the actions taken by the Association of American Medical Colleges in regard to this problem, which will be discussed in Louisville, where Dr. Smillie is in attendance.

Another organization with which your committee has established a fruitful relationship is the Association of Schools of Public Health. Our Subcommittee on Field Training Centers has already made plans for joint consideration of its problems. The committee has thus cultivated studies and discussions beyond its immediate purview.

There are now pending before your committee reports dealing with the educational qualifications of health educators, laboratory personnel, maternal and child health specialists, specialists in mental hygiene and in cancer control, and public health dentists. These reports have been prepared in accordance with our newly adopted policy, and it is anticipated that by this time next year we shall be prepared to ask for your approval of them.

During the year two new subcommittees were set up, one to deal with qualifications of school physicians and the other with executives of voluntary health agencies. Both of these are already at work on the preparation of their reports.

While no conclusion has yet been

* A.J.P.H., 32, 5:534 (May), 1942.

reached as to whether the certification of all public health personnel is a proper function of this committee, nevertheless serious consideration is being given to an interesting project developed several years ago by the Canadian Public Health Association for certifying sanitarians. We shall have more to report on this subject at a later time.

The Governing Council is not unfamiliar with the beginnings of the Merit System Study which have been reported at two previous meetings. The Governing Council, the Executive Board, and the Committee on Professional Education have all been emphatic about the importance of such a project in order that the present effort to implement merit systems in each of the states may not fail. It is a pleasure to report that during the last year this project has become productive and preparation of examinations in the first of the public health specialties has been undertaken.

Through agreement with the original sponsors of this project, the U. S. Children's Bureau and the U. S. Public Health Service, it has been decided that the Association should focus on the preparation of examination materials for use by the state merit system councils. With the assistance of several cooperating state health officers, and through the Conference of State and Territorial Health Officers, funds adequate for the first year have been made available for this project and the federal services have been generous in loaning personnel and providing other assistance.

Systematic work since the first of the year 1942 by a staff of subject matter consultants and a test technician has resulted in the preparation of an excellent list of items for public health nursing personnel which are now available to the number of about 2,000.

Even more important, however, has been the educational process by which members of the public health profession have become familiar with modern methods in personnel administration and in examination technics, so that groundwork has been laid by which items in many other fields can the more rapidly be prepared. Staff members of this unit are present at the Annual Meeting, prepared to counsel with those in the several states having responsibility in this field, and it is apparent that there will be a considerable demand for these services in the immediate future.

The attention of the Council is called to the fact that this procedure under the auspices of a professional society is unique and it is hoped that the quality of the resulting examinations will justify the confidence which the responsible federal agencies have placed in the American Public Health Association.

With the funds already available, and in anticipation of contributions to be made by the states that use the service, the committee plans to proceed with examination materials in the fields of administration, environmental sanitation, and the laboratory.

The Committee on Professional Education has pride in presenting this progress report of a very concrete service to the public and to the profession.

As the Committee on Professional Education enters its eleventh year, we do so with confidence in the future of professional education, not only for ourselves but for all those peoples to whom democracy is a cherished ideal. Again we are grateful that we have been given the opportunity to make some contribution to the lofty objective of this professional society—the protection and promotion of the public health.

W. P. SHEPARD, M.D., *Chairman*

Research and Standards*

THE year through which we have just passed has been one of increased activity for the members of the public health profession. Many of those who have served on this committee and who have contributed to the work of its subcommittees have been called to the armed forces. They have taken with them many of the technical procedures with which this Association can be credited and are making their benefits available to the war effort.

The Report of the Executive Board to the Governing Council has covered many of the items with which this committee is concerned. Among them are the extensive use by the Army and Navy of *Standard Methods for the Examination of Water and Sewage* and *Standard Methods for the Examination of Dairy Products*. The volume on *Diagnostic Procedures and Reagents* has been micro-filmed and flown to China for use in war areas. A new edition of this highly useful book is now being prepared and its scope will be extended by the addition of a number of referees who have been invited to prepare manuscripts.

You have already learned of the condensed version in Spanish of the volume on dairy products which is now under consideration. The *Report on the Control of Communicable Diseases*, to which we added our approval in 1940, is proving to be of great value in the emergency. *Recommended Practice for Design, Equipment and Operation of Swimming Pools and Other Bathing Places*, which this committee and the Governing Council approved at the last

Annual Meeting, continues to fill a real need. Plans are now well along for a new edition of *Standard Methods for the Examination of Water and Sewage*.

There is now before your committee a revised report on *Recommended Methods of Procedure for the Examination of Shellfish and Shellfish Waters*. In conformity with the policy of this committee, ample opportunity has been afforded to interested persons and groups to criticize and comment on the report, and we have provided for an open discussion of the subject at the committee's meeting here.

We are pleased to report that, at the suggestion of this committee, the American Standards Association has revised its specifications for drinking fountains to conform substantially with those adopted by this Association. This step will eliminate much of the confusion that has existed in the field.

The Standard Methods Committee for Frozen Desserts and Ingredients of the Laboratory Section has circulated widely new proposed methods, and if these meet with general approval they will be incorporated in the next edition of *Standard Methods for the Examination of Dairy Products*.

The study of autopsied deaths being conducted by the Subcommittee on Autopsies is continuing but, owing to lack of further funds, will have to be completed when fifty thousand protocols have been abstracted by the end of January, 1943. A second contribution of a statistical nature will be presented at this meeting at a session of the Vital Statistics Section.

During 1942, the Subcommittee on the Hygiene of Housing, under Dr. C.-E. A. Winslow's able leadership, has

* Report of the Chairman of the Committee to the Governing Council, October 26, 1942.

concentrated on two lines of work intended to develop needed administrative tools for public health departments and other official bodies concerned with housing: (a) completion of the technic for appraisal of housing deficiencies in low-grade urban areas; (b) study of principles and practice in the field of housing regulation under the law.

The results of the application of the recommended appraisal technic as applied in three test areas, one each in New Haven, Waterbury, and Stamford, Conn., have been published in the weekly *Public Health Reports*.¹ The technical secretary of the subcommittee will present the finished study at this annual meeting of the Association.² A statement on the essential principles of housing regulations under the law will be made by Professor Winslow at the current Association meeting.³

Other committee publications and research during the year have included the following: (a) "New Light on the Relation of Housing to Health," (b) a study of the performance of inexpensive heating units in two experimental houses of the John B. Pierce Foundation, (c) "Essentials of Space Planning and Space Organization in Dwelling Units," (d) the pilot study of family living functions as affected by contemporary housing design, conducted with the Pierce Foundation.

Agencies responsible for the Govern-

ment's war housing program have requested the subcommittee's advice or informal assistance in several matters during the year, including the revision of standards for war housing, the development of standards for dormitory types of temporary housing, and the formulation of housing standards for the billeting of war workers.

This completes the 13th year since the Committee on Research and Standards was established. While it has not occupied the broad field contemplated by some of those who outlined its charter, it has afforded a mechanism for bringing together at the Association level representatives of the several sections and of other organizations to consider technical matters of mutual interest. It has stimulated the formulation and constant revision of standards and of recommended procedures in the technical fields of public health, and served in a judicial capacity to advise the Governing Council concerning their endorsement by the Association. I believe that it should be continued.

KENNETH F. MAXCY, M.D.,
Chairman

Eligibility*

THE Committee on Eligibility is representative of each of the ten Sections of the Association. The members serve for a period of two years, five being elected annually by the Sections and confirmed by the Executive Board. The Executive Board also appoints an additional Fellow to serve as Chairman. The duties of this committee are to pass upon the eligibility of Fellows, members, and other constituents in accordance with the provisions of the By-Laws.

In view of the fact that membership in the Association carries no voting privileges and because there are no professional qualifications for membership, it becomes necessary for the Committee on Eligibility only to make sure that no persons are elected to membership who could be said to be a discredit to the Association. The consideration of eligibility for Life Membership, for Sustaining Membership, and for Honorary Fellowship is not arduous. The important task of the committee relates to testing the eligibility of Fellows and of screening the applications for election of Affiliated Societies.

Two years have elapsed since the By-Laws of the Association were changed by the Governing Council to make more specific and more rigid the requirements for Fellowship in this professional society. The Committee on Eligibility has taken seriously the request of the Governing Council to test each application strictly by the provisions of the By-Laws. This is no mean task, involving as it does the review of well over a hundred applications after they have passed through the Section Councils,

and involving the exercise of considerable judicial discretion.

We note with interest the fact that raising the standards for Fellowship has not decreased the number of applications. Beginning with 1937, the annual number of Fellows elected was as follows: 60, 101, 77, 113, 123, and this year there are 139 applications. The average declinations by the Section Councils and the Committee on Eligibility has run about 8 per cent.

The number of membership applications last year totaled 1,034, of whom all were approved. This compares with the total of 836 for the previous twelve month period, an increase of nearly 25 per cent, contributing to the all-time high in Association membership.

At this meeting the Committee on Eligibility has reviewed the qualifications of 135 Fellowship applicants who had been previously approved for Fellowship by the various Section Councils and by the Executive Board, acting on applicants for unaffiliated Fellowship. Of this number, 133 have been approved by the committee, and their names appear on the list that has been furnished to each member of the Governing Council. It now becomes the function of the Governing Council to determine whether these individuals shall be admitted into the Fellowship of the American Public Health Association. The Committee on Eligibility after careful consideration recommends each of these names for your approval.

The committee has also approved six applications for Life Membership and the names of these applicants will also be found on the list before you. They are recommended for election to Life

* Report of the Chairman of the Committee to the Governing Council, October 28, 1942.

Membership by the Governing Council. Under our established policy this status is regarded in terms of its economic significance rather than in terms of an honorary significance.

The committee has carefully studied the routine for election of Honorary Fellows, and we are of the opinion that clarification is necessary in order to determine the proper place of the Sections in nominating individuals for this honor. The Committee on Eligibility recommends for consideration and approval of the Governing Council the following routine for the election of Honorary Fellows:

For persons who are members or Fellows of the A.P.H.A.

1. A resolution may arise from the Council of the Section with which a person is affiliated, or from the Executive Board, or upon the initiative of the Committee on Eligibility itself, suggesting the election of the individual as an Honorary Fellow. This resolution, in any case, to receive the consideration of the Committee on Eligibility.
2. The Committee on Eligibility considers the recommendation of the

Section Council or of the Executive Board and passes on its recommendation to the Governing Council for final action.

For persons who are not members or Fellows of the A.P.H.A., a resolution may arise from any Section Council, from the Executive Board, from the Committee on Eligibility, or from the Governing Council itself, but it shall be established as a policy that such recommendations shall be referred to the Committee on Eligibility for consideration before the individual is elected.

The Committee on Eligibility respectfully recommends to the Governing Council the election of the following persons to Honorary Fellowship in the Association:

William M. Frazer, O.B.E., M.D.

E. R. A. Merewether, M.D.

Sir John Boyd Orr, F.R.S., LL.D.

The Committee on Eligibility also recommends to the Governing Council that those persons in attendance at this Annual Meeting as invited guests under the auspices of the Pan American Sanitary Bureau be recommended for Honorary Membership.

DON W. GUDAKUNST, M.D.,

Chairman

American Museum of Hygiene*

ASSOCIATION COMMITTEE

EACH year since its appointment this committee has closed its report to this body with a recommendation that it be continued. This year, with great reluctance we omit that recommendation.

It will be recalled that we were appointed to promote the development of Museums of Health in America. Our progress has been previously reported. Museums of Health now exist in Cleveland and New York. Germinal interest in the establishment of museums in other cities has been submerged by the immediate necessities of war. Community leaders who in ordinary times could be counted on to advance the development of this newer instrument of health education have been called to other urgent tasks. Our committee members are similarly affected.

With two museums now established and the perennial concern of this Association in problems in health education, we can confidently assume that

when the present world difficulties have been resolved, and a new postwar era offers new opportunities for new enterprises, the Governing Council and Executive Board will be eager to establish a new committee to carry on and to capitalize on the pioneer efforts of this committee.

In thus recommending that the Association temporarily halt one of its most progressive undertakings, the committee records its appreciation of the support and coöperation which the Association has given to it at every step in the way.

BOOKS AND REPORTS

Annual Book Review

MAZÏCK P. RAVENEL, M.D.

"Books are the legacies that genius leaves to mankind, to be delivered down from generation to generation, as presents to those that are yet unborn."—ADDISON

THE war has left its impress, not only on the number of books issued during the past year, but on their character. While there has been a great deal of writing on military topics, a large part of it has not yet reached the book stage. There have been some revisions of books particularly useful in wartime which have been brought up to date and some of the newer methods described. There have also been a large number of pamphlets issued by official bodies, most of them designed for instruction of the civilian population and the many war agencies which have been created.

As heretofore, our chief guide has been our own JOURNAL, but we have regularly examined a number of other journals, especially *The Lancet* and *British Medical Journal*. The valuations of the books mentioned are those given by the reviewers in one or more journals, often in the words of the reviewers.

BIOGRAPHY AND HISTORY

Under this heading there are a number of unusually interesting works many of which are timely. *Medical Work of the Knights Hospitallers of Saint John of Jerusalem*, by Edgar Erskine Hume, Johns Hopkins Press, is an excellent presentation of that remarkable body of men which has existed since the 11th century who made their way "across land and sea through the centuries protecting crusaders in medieval days or Spanish refugees today—any and all who needed help." Their hospitals were models for the world to follow; even in World War II one of their ambulance units was the first to come to the aid of the victims of "The Athenia." *Fatal Partners: War and Disease*, by Ralph H. Major, Doubleday, Doran, is particularly timely as pointing out some of the darkest lessons of war. The author is well known for his historical research. He admits that war provides for the doc-

tors a vast laboratory in which to study the practical effects of the application of their knowledge, but holds that war in itself has contributed nothing to medicine. One lesson the book teaches is that our Army Medical Library remains the most comprehensive and efficient repository of knowledge useful in medicine in the whole world. *The Golden Jubilee of the Association of Military Surgeons of the United States—A History of Its First Half Century, 1891-1941*, by Edgar Erskine Hume, Association of Military Surgeons, is, of course, of primary importance to the members of the Association of Military Surgeons, but should be of interest to all, since it shows the important part played by this Association in the development of military medicine, and especially its work for preparedness during the half century of the Association's existence. Historically it is also interesting as giving photographic cuts of all the Presi-

dents and editors of the journal published by the Association, and also some facsimiles of documents and title pages of documents of historical interest. The appearance of *The Life of Florence Nightingale*, by Sir Edward Cook, Macmillan, is peculiarly timely in view of the impetus which the present war has given to tropical medicine and to military medicine. The history of Florence Nightingale is always valuable reading for all classes of people. She has been referred to as the "mother both of military and of tropical medicine." *Doctors Anonymous, The Story of Laboratory Medicine*, by William McKee German, Duell, Sloan and Pearce, is a frank plea for the recognition of the pathologist whose work has such a foundational relation to every branch of the practice of medicine and yet whose name so seldom appears. This book is highly recommended to the profession as well as to the laity. *The Man Who Lived for Tomorrow*, by Wade W. Oliver, Dutton, is intended for a biography of the late William Hallock Park, who perhaps was the most beloved bacteriologist America has produced. In spite of some shortcomings, it is, so far, the best biography of Park which has appeared and can be recommended as a tribute to that widely known man. *The American and His Food*, by Richard Osborn Cummings, University of Chicago Press, is a systematic account of food habits during the past century. It is pleasingly written and can be recommended to physicians, health workers, nutritionists, nurses, and intelligent readers of all classes. *The Value of Health to a City—Two Lectures Delivered in 1873 by Max Von Pettenkofer*, Translated by Henry E. Sigerist, Johns Hopkins Press, shows vision, marshalling of all forces, medical and scientific, to prevent disease. It represents the work of a pioneer medical statesman. *Four Treatises of Theophrastus von Hohen-*

heim Called Paracelsus—Translated from the original German, with introductory Essays by C. Lillian Temkin, George Rosen, Gregory Zilboorg, Henry E. Sigerist—Edited, with a preface by Henry E. Sigerist, Johns Hopkins Press, can be highly recommended, and the translation is good. A name which always appears in medicine is that of Paracelsus, who was something of a mystic but quite an observer, and his observations are credited with being the origin of industrial medicine and hygiene. *The Doctors Mayo*, by Helen Clapesattle, Introduction by Dr. Guy Stanton Ford, University of Minnesota Press, gives an interesting story of the three Mayos—father and two sons, who made a tremendous impress on medicine in America. That part of the book concerning the elder Dr. Mayo is extraordinarily successful. That concerning the sons is too highly colored and some reviewers have regretted that publication could not have been delayed "until all the pigments could be employed." *Doctor Bard of Hyde Park*, by John Brett Langstaff, Dutton, is a story of one of the famous physicians of Revolutionary time—a man who saved Washington's life on one occasion. He was the first American to write seriously of diphtheria, 1771. Not only was he a leading physician but also a striking figure in the early history of this country. *Life and Teaching of Sir William Macerwen*, by A. K. Bowman, William Hodge, gives a history of the life, both physical and mental, of one of England's great surgeons, who was also a great teacher. In the last ten years of his life he gave distinguished war service and was also President of the British Medical Association. *Memorable Days in Medicine. A Calendar of Biology and Medicine*, by Paul F. Clark and Alice Schiedt Clark, University of Wisconsin Press, is useful as a book of reference for dates and biographies. *Source Book*

of *Medical History*, by Logan Clendenning, Hoeber, is a compendium which spans the period from 1900 B.C. to 1895 A.D. It is a valuable book of reference, each chapter being preceded by a brief discussion of the period dealt with.

CHEMOTHERAPY AND SERUM THERAPY

The year has been noted for advances in chemotherapy, especially in the development of the "sulfa" drugs. The government has decreed sulfathiazole as a "must" treatment for gonorrhea in men in the services and there is continued use of some of the derivatives in the pneumonias. Most of this material is found in current journals and has not reached the book stage. However, we can report: *The Sulfonamide Compounds in the Treatment of Infections*, by Maurice A. Schnitker, Oxford University Press. This has been reprinted from Oxford Loose-Leaf Medicine. It gives the history, chemistry, and pharmacology of these compounds, also describes methods of administration, dosage, toxic effects, etc. It has brief reviews on other chemotherapeutic agents such as prontosil and its derivatives. It is not a treatise, but is sufficiently complete and accurate "to satisfy the harassed student, the busy practitioner, and the hurrying lecturer."

CHILD HYGIENE AND TRAINING

War conditions have made the care of children more than usually important if possible. There have been a large number of pamphlets and short articles on the various aspects of child care. Among the books which have appeared may be mentioned: *Delinquency Control*, by Lowell Juillard Carr, Harper. This is the outcome of a large experience and much study at the Michigan Child Guidance Institute. The book is a good guide and an inspiration to anyone seeking practical

suggestions. From the public health concept it treats not only of control but of prevention. *Solving School Health Problems*, by Dorothy B. Nyswander, The Commonwealth Fund, is a "must" book for health officers, school superintendents, and directors of school health services. It is the outcome of four years of intensive study in New York City. *The Family in a World at War*, edited by Sidonie Matsner Gruenberg, Harper, deals with the various phases of family life in relation to the war emergency and national defense. The "Children's Charter in Wartime" has been prepared by a Commission on Children in Wartime of the U. S. Children's Bureau. The book can be thoroughly recommended for wide reading, especially at this time. The editor is to be congratulated in bringing together such useful material when the preservation of the family is of paramount concern. The origin of the book and the various organizations which have taken part in its production as well as the names of the special authors assure one of its value as well as its validity. *Developmental Diagnosis—Normal and Abnormal Child Development*, by Arnold Gesell and Catherine S. Amatruda, Hoeber, cannot fail to have a profound influence upon methodology in the study of young children and upon the supervision of their health and development based upon exact and exhaustive observations. It is of more than passing interest and will serve as a volume of reference for some time to come.

ENGINEERING

Engineering has always been one of the most useful branches of public health. We are especially dependent on the engineers in this time of war not only in protecting our men in the field, but also for conserving the health of the civilians at home. *Refuse Collection*

Practice, by the Committee on Refuse Collection and Disposal, American Public Works Association, is the first comprehensive treatise on this subject since 1921. It is complete and authoritative. *Water Purification for Plant Operators*, by G. D. Norcom and K. W. Brown, McGraw-Hill, is an instruction book for performance of routine duties by plant operators. It is a useful book in its field. *Public Works Engineers' Yearbook 1942*, American Public Works Association, contains more than 30 authoritative articles on subjects in which every engineer is interested. Both administrative and technical aspects of the problem are discussed. It can be recommended highly for administrators, libraries, public works engineers, and officials.

HEALTH EDUCATION

It has been pointed out many times that if we could convince the public of the truth and daily importance of facts which are already well known and abundantly proved, thousands of lives and much illness could be saved, and this means that in the aggregate many thousands of man power days could be added to our production. We therefore welcome *Health Education of the Public*, by W. W. Bauer and Thomas G. Hull (2nd ed.), Saunders. New chapters have been added, including one on Philosophy of Health Education and one on Training and Qualifications. This second edition of a well known book will give valuable assistance and stimulus to all interested in public health.

HOUSING

Housing has a special interest on account of the conditions in the country, the moving of great numbers of men with their families to centers of manufacture, ordnance, etc., with new settlements partaking of the nature of villages and towns springing up in

widely separated areas. *Housing Yearbook—1942*, National Association of Housing Officials, Publication No. N 159, is a valuable compilation of articles on housing progress by various authorities. It is useful in considering the changes brought about in connection with housing agencies and activities by the federal authorities, the Navy, etc. Although omissions have been made on account of economy, the book is a standard for all interested in this subject.

IMMUNITY

With the men of our armed forces being scattered to the four corners of the earth, immunization against various diseases has become a prominent feature of preparedness. It is rather surprising that we have only one book to report: *Immunization to Typhoid Fever*, by Colonel J. F. Siler and others, Johns Hopkins Press. This covers seven years' experimental studies made in the Army Medical School research laboratories and is an outstanding contribution to our knowledge of immunization against typhoid fever. There is nothing else like it in this country.

INDUSTRIAL HYGIENE

This is another subject the importance of which has been greatly increased on account of war activities, with its multitude of new processes, new chemicals and combinations, all of which are closely related also to the housing problem and migration of workers. *Occupational Diseases*, by Rutherford T. Johnstone, Saunders, is useful to the general practitioner as well as specialists in the field of industrial medicine. Its publication is very opportune in this time of national emergency. *Eye Hazards in Industry*, by Louis Resnick, Columbia University Press, has been published for the National Society for the Prevention of Blindness and is timely in view of the

increase in industrial accidents during the last two years as reported by the Bureau of Labor Statistics and the National Safety Council, which say that 300,000 eye injuries occurred yearly in industrial fields, costing employers and the injured workmen more than a hundred million dollars. It is held that only 2 per cent of this enormous loss may be considered as unavoidable. The book can be highly recommended.

MENTAL HEALTH

We have not seen any outstanding new book on mental health. However, the selection of men for all of the services has been more exacting and the training periods have in view the prevention, as far as possible, of some of the breakdowns always seen at such a time as this.

NURSING

We might well have put the biography of Florence Nightingale under this heading. No one needs to be told of the importance of nursing and the part nurses play in a war. A very timely book is: *The Public Health Nurse in Action*, by Marguerite Wales, Macmillan. The author reaffirms her belief in the importance of the work of the public health nurse, calling her "a galvanizing agent." This is a most interesting and valuable presentation of the whole subject. *Nursing: An Art and a Science*, by Margaret A. Tracy (2nd ed.), Mosby, has been revised with the object of making it more useful as a textbook for student nurses. It can be recommended for use in schools of nursing and as a reference book for public health nurses. *Nursing: A Community Health Service*, by Amelia Howe Grant, Saunders, will serve the needs of many groups and individuals, and especially graduate nurses preparing for public health nursing and for

students in the basic nursing education programs of study.

NUTRITION

There is no need to stress the importance of good nutrition at this time. The slogan of the first World War was "Food will win the war." Now there seems to be no question that we are using food not only to win the war but to win and hold friends in practically every part of the world. The tremendous demands taxing our resources make the whole subject of great importance. The following books have been reviewed: *Nutritional Deficiencies*, by John B. Youmans, assisted by E. White Patton, Lippincott, was written primarily for practitioners. It should be read by all physicians and particularly teachers of medicine and nursing. The book can be recommended as an accurate and authoritative source of information. *We Need Vitamins*, by Walter H. Eddy and G. C. Hawley, Reinhold, is one of the best books on vitamins—accurate and written in non-technical language so that the average lay person can understand it. So many things are being learned about nutrition and the vitamins that a book is scarcely printed before it becomes more or less out of date. However, this book can be recommended without reservation, especially for dietitians, though all doctors will find much of value in it. It should be a wholesome tonic against the reckless exploitation of vitamins which is going on in this country. *Modern Bread from the Viewpoint of Nutrition*, by Henry C. Sherman and Constance S. Pearson, Macmillan, is by one of the best known authorities and brings the matter up to date. Modern bread is very different from what "mother used to make." It is almost all "enriched" with an eye on mineral and vitamin content as well as the calories per pound. The book should have wide reading.

Food and Drug Regulations, by Stephen Wilson, American Council on Public Affairs, gives a complete story of food and drug legislation of the federal government. The book gives important facts, incidents, and excerpts of the bitter debates leading up to and through the passage of the Federal Food and Drug Acts of 1906 and 1938. A whole chapter is given to the history of food and drug legislation from the days of the Athenians and Romans to the passage of Pure Food and Drug Act of 1906. *Chemistry and Physiology of the Vitamins*, by H. R. Rosenberg, Interscience Publishing Company, is perhaps the most complete record of work done in the field of vitamins up to 1942. The subject matter is "critically and comprehensively appraised from chemical, physiological, nutritional, and industrial points of view. The book "should be heaven-sent to teachers of biochemistry, nutritionists, clinicians, and even to vitamin-plagued laymen." *The Biological Action of the Vitamins*, edited by E. A. Evans, Jr., University of Chicago Press, contains the fourteen papers presented at the symposium on The Biological Action of the Vitamins, held in connection with the 50th anniversary celebration of the University of Chicago in 1941. It is the best single source of information on these aspects of the vitamins now available. *Tables of Food Values*, by Alice V. Bradley, Manual Arts Press, is extremely useful to both scientists and lay persons concerned with the vitamin and other nutrient values of food.

ORAL HYGIENE

Oral hygiene is another subject of great importance at all times but being emphasized in examination of men for the armed services. Napoleon said: "An army travels on its belly." With almost equal truth it travels on good teeth, as they play such an important part in nutrition. The output of books

on the subject is again scant for this year, and we can mention only: *Professional Dentistry in American Society*, by Alfred J. Asgis, Clinical Press. The author considers the relation of the profession to society at large and emphasizes some of the responsibilities of one to the other. It is particularly recommended to health workers who are not dentists as stressing the integration of dental activities in a general public health program.

PARASITOLOGY

It may become tiresome to our readers to repeat so much and perhaps we should have headed the general article by saying that all the topics considered are of more than usual interest at this time. It is true, however, that certain subjects have been brought to the fore by the fact we are waging a world war, and for the first time in our history we have three branches of the service—Army, Navy, and Marines — with the necessary nurses and lay personnel, living in the tropics under conditions which are new, not only to our forces but to practically every American, except here and there an explorer. From all accounts the average person has no conception of what insects generally, and parasites in particular, mean to soldiers in the jungles—the South Sea Islands, for example. *Textbook of Clinical Parasitology*, by David L. Belding, Appleton-Century, is a comprehensive and reliable reference for those dealing with animal parasites and the pathological conditions produced. It can be thoroughly recommended to students of tropical medicine, medical men, and laboratory workers.

PUBLIC HEALTH

There have been few notable books on public health as such. However, some useful ones have appeared as well as some new editions and a number of

articles treating of the various subjects which pertain in one way or another to health. We can mention particularly: *Handbook of Communicable Diseases*, by Franklin H. Top and Collaborators, Mosby, which is a convenient compendium for health officers, interns, medical students, and nurses. *Encephalitis: A Clinical Study*, by Josephine B. Neal and Associate Authors, Grune and Strattan, surpasses the expectation of the most critical reader. It contains a wealth of information on each individual type of the large group of known encephalitides. There are more than a hundred selected case histories and 600 references arranged in sequence at the end of each subchapter. It is a "must" book for every library and public health worker, written in clear style, and set in beautiful type. The book fulfils a need that has long existed in medicine and public health. *Communicable Disease Control*, by Gaylord W. Anderson and Margaret G. Arnstein, Macmillan, is designed especially for health officers and public health nurses. It is written from the wide experience of the authors and is a useful summary of American practice, bringing together in a unique manner the functions of the health officer and public health nurse. It can be highly recommended to all workers in communicable disease control.

PUBLIC HEALTH AND THE WAR

This year we have used this heading, as a number of publications, mostly pamphlets or leaflets, have appeared under competent authority, devoted to war work. We can recommend: *Handbook for Civilian Defense*, by H. Mayer-Daxlanden, Civilian Advisory Service. Throughout a large part of the country the excitement over air raids seems to have passed; however, there is still reason for preparedness. In 1941 the Rose Bowl game and other gatherings were cancelled. In 1942 all

the Bowl games took place, and we do not hear nearly so much of defense against air raids. The reviewer of this pamphlet recommends also, *Civil Air Defense*, by Lt. Col. A. M. Prentiss, of the U. S. Army; also more recent publications of the U. S. Office of Civilian Defense, the *Handbooks, Textbooks, Planning and Training Guides*, and *Bulletins*, British Library of Information, 30 Rockefeller Plaza, New York. *Preventive Medicine in Modern Practice*, edited under the auspices of the Committee on Public Health Relations of the New York Academy of Medicine, Hoeber, contains chapters written by a number of men, all experts in their respective fields. It is a discussion of the problems of preventive medicine which are "encountered by the physician in his daily practice, and in so far as possible, the presentation of solutions of these problems." It is authoritative. *War Gases*, by Morris B. Jacobs, Interscience Publishers, is most timely and especially useful to all concerned in civilian defense. With the possibility of the use of poison gases in the present war, defense against chemical war agents grows in importance. *Digest of State and Federal Laws Dealing with Prostitution and Other Sex Offenses*, compiled under the direction of Bascom Johnson by George Gould and Roy E. Dickerson, American Social Hygiene Association, shows the confusion which exists both in legislative bodies and among the public. It contains much practical knowledge of the means of prevention. This digest is of especial value to public health workers, legislators, and research workers. *Fundamentals of Anesthesia: An Outline*, by Subcommittee on Anesthesia of National Research Council, American Medical Association Press, discusses at some length in outline form the question of complications, as well as comfort and transport of the wounded. War gases are also named and dis-

cussed. *The Management of Fractures, Dislocations and Sprains*, by John Albert Key and H. Earle Conwell (3rd ed.), Mosby, is excellent and should be in the library of every physician and surgeon, especially during wartime. In the present edition extensive changes have been made and other chapters rewritten to bring the subject matter up to date. *War Injuries of the Chest*, edited by H. Morrison Davies and Robert Coope, E. and S. Livingstone, is a sound expression of thoracic practice at the present time. The chapter on anesthesia is able. *Surgery of Modern Warfare*, edited by Hamilton Bailey (2nd ed.), Volumes I and II, William Wood, represents British surgery at its best, depicting actual wartime surgical practice. The volumes are beautifully and lavishly illustrated. The illustrations alone are a liberal education in modern surgery. It would be hard to pick any one section which is better than the others, but "Shock and Its Treatment," "Skin Grafting in Wounds Involving Skin Loss," "Wounds of Arteries," and "Wounds of the Face and Jaws" are outstanding. Such practical and efficient directions on important phases of the treatment and management of wounds of the face, jaws and neck are seldom found. "This book depicts a new world in war medicine and surgery." *After-Treatment*, by H. J. Atkins, Blackwell, is especially good in its emphasis on human side of treatment and the common-sense approach to problems of convalescence. It is one of the best and most attractive on the subject. *The Blood Bank and Technique and Therapeutics of Transfusions*, by Robert A. Kilduffe and M. DeBaakey, Mosby, covers a wide scope. It is a good history of the subject, is well produced, and informative. The appearance of this book is timely. *Medical Manual of Chemical Warfare*—Including also An Atlas of Gas

Poisoning, Reprinted by Permission of the Controller of His Britannic Majesty's Stationers Office, Chemical Publishing Company, Inc., is an official release from the British office. Its value is enhanced by the inclusion of plates in colors. It is heartily recommended as an authoritative guide in the handling of a destructive agent of war with which we have so far not had to deal. *War Medicine. A Symposium*, edited by Winfield Scott Pugh, Philosophical Library, Inc. This book is a collection of outstanding articles on military medicine grouped in three sections: surgery, aviation and naval medicine, and general medicine. The articles for the most part are by English and American authors, either given entire or are abstracted. The material is concise and factual. There are articles on certain parasites and on problems in psychiatry peculiar to military personnel. The book deserves study by physicians engaged in military medicine and civilian physicians in private practice who expect to enter the service.

TEXTBOOKS AND NEW EDITIONS

Textbooks and new editions are always looked for with interest. A revised edition is often better than the original, and should be, as most authors take advantage of the criticisms and suggestions by reviewers. The following may be mentioned: *Personal Hygiene Applied*, by Jesse Feiring Williams (7th ed.), Saunders, has been fundamentally revised and brought up to date, containing new sections on vitamins, specific diseases, etc. It is an excellent and standard book. *Standard Methods for the Examination of Dairy Products* (8th ed.), American Public Health Association, is the culmination of 36 years of study by specialists, and has been brought up to date. It is indispensable. *Stitt's Diagnosis, Prevention and Treatment of Tropical*

Diseases, by Richard P. Strong (6th ed.), Blakiston, is particularly welcome to all interested in this field of medicine which is of so much importance to our national defense in the present war. Its appearance at this time is most welcome and it should be in the possession of all medical libraries, teachers of the subject, and medical units in the armed forces. *Industrial Surgery*, by Willis W. Lasher (rev. 1st ed.), Hoeber, is an excellent book which covers the whole field of industrial surgery. It is especially to be recommended at this time when industry is geared for the tremendous war effort, and industrial surgery is a most vital subject. It is recommended therefore not only to those specializing in industrial medicine but to the general practitioner as well. *The Modern Treatment of Syphilis*, by Joseph Earle Moore (2nd ed.), Thomas, is a valuable compilation of the literature. Apart from the actual treatment, this book gives advice concerning the venereal disease control officer, "who should combine in himself public health experience and a wide clinical knowledge of syphilis." It is especially timely when the venereal disease question is playing such a large part in the making of our army. *Handbook of Hygiene*, by Joseph W. Bigger (2nd ed.), Williams and Wilkins, is presented in a clear-cut, concise manner and the material is well arranged. The first edition was well received, and the second maintains the standard and is brought up to date. *The Sanitary Inspector's Handbook*, by Henry H. Clay (5th ed.), H. K. Lewis & Co. A book that has reached its fifth edition in ten years must have something a little better than usual. The author is a Major in the R.A.M.C. This wartime edition includes a special reference to "conservancy" and to camp and rural sanitation, bringing the material up to date. While written from the English standpoint, every edition of the book

has had good reception in this country. This one has an introduction by Sir Wilson Jameson, who points out that the sanitary inspector has become more highly specialized and technical within the British Empire than anywhere else in the world. *Community Hygiene*, by Smiley and Gould (3d ed.), Macmillan, is a standard book streamlined and brought abreast of the times, and is excellent.

TUBERCULOSIS

Tuberculosis is always with us, and already there are signs of an increase in the incidence of the disease due to war conditions. *The Story of Clinical Pulmonary Tuberculosis*, by Lawrason Brown, Williams & Wilkins, is to be especially recommended. Published posthumously, it is by one of the masters in the study of tuberculosis, a victim of the disease himself. Containing much history, it is much more than a story of tuberculosis. Dr. Brown was almost as well known in connection with Saranac Lake as was Trudeau, the founder. Always a careful student, few men have ever been more widely beloved. The book will be useful to all physicians, whether specialists or not. *Tuberculosis in Industry*—Report of the Symposium Held at the Saranac Laboratory for the Study of Tuberculosis, Saranac Lake, N. Y., National Tuberculosis Association, is a timely book in view of the pressure under which industries are now operating. Reduction in deaths in the industries has paralleled that in the general population. It is fifth in importance of all diseases and accounts for 6.5 per cent of deaths among workers. Under the etiology of tuberculosis silicosis was naturally considered. Only those dusts high in free SiO_2 are known to alter appreciably the susceptibility to tuberculosis. Education was stressed and early case discovery is regarded as the key to prevention.

MISCELLANEOUS

There are always a number of books which are hard to put in one little compartment so we have taken the best of them and put them under the meaningless title of "Miscellaneous." The following can be recommended: *Strange Malady*, by Warren T. Vaughan, Doubleday, Doran. This is a history as well as a discussion of allergy with only a brief section devoted to treatment. Certain reviewers believe that the book is misleading in that it states sensitization to foods is the commonest form of human allergy. Experts in allergy and in internal medicine will be inclined to criticize this statement. With this exception the book is up-to-date and correct. It is well written and the illustrations, while amusing, portray accurately many of the complicated problems of immunity. *Administrative Medicine*, edited by Haven Emerson, Nelson, combines treatment of the field of public health and medical care in one volume, and under a new name. Fifty-six authors have taken part in the making of this book. The section on public health will prove particularly attractive for readers of this JOURNAL, though there is something for all interested in public health from any standpoint. It is a real contribution to the scant literature of the subject. *The Anaerobic Bacteria and Their Activities in Nature and Disease* (A Subject Bibliography), by L. S. McClung and Elizabeth McCoy, University of California Press, is Supplement I Literature for 1938 and 1939. It is a book necessary for all libraries and should be in all medical schools. *About Ourselves*, by James G. Needham, Cattell Press, is an unusual book, written by a biologist. It is pessimistic inasmuch as he says that man is so much of an animal that war appears to be inevitable. It is a most useful book for study by all educated people who wish to know more about that curious com-

plex we call "homo sapiens." *Speaking of Man*, by Michael F. Guyer, Harper. At first sight one might wonder why a book by a biologist should be especially useful at a time like this, but both the author of *About Ourselves* and this book refer to war and describe man as belonging to the fighting animals. Guyer says: "And since war is outstandingly a biological phenomenon the biologist's views concerning struggle in nature, about competing social systems, and above all, regarding that combative social animal, man, may be worth considering by thoughtful folk who seek a peaceful world. As is true of practically all animals where the male is the larger, stronger, better armed and more highly ornamented, man is by nature a fighter." *Behind the Mask of Medicine*, by Miles Atkinson, Scribner, an unusually good study of the many problems which confront the physician in his practice, considering them from the historical, religious, sociological, and practical points of view, which should be in the library of every physician. It would be well if the public could be induced to read it widely. The author "inculcates the highest standards of conduct under every circumstance which may confront the doctor either as a physician or man." *The Microbe's Challenge*, by Frederick Ebersson, Jacques Cattell Press, is an unusually well done popular story of bacteriology and many of its accomplishments. It is one of the best summaries of the subject matter which has ever been written. *Rabies*, by Leslie T. Webster, Macmillan, intended for students, research men, physicians, and veterinarians, though especially designed for those having some knowledge of the disease, who should in turn, pass it on to the laity to dispel the superstitions and myths which are so widely spread. Apart from its scientific character and the result of the author's research, the

book contains in addition much good sense and a lot of practical knowledge.

Any attempt to select books for special attention will be immediately subject to attack. Omissions of certain titles will be regarded as serious by some; others will feel that one or another book is distinctly not worthy of

mention. Criticism of over-emphasis on one category and neglect as to another may be expected. While the selections in this article are the writer's, the comments in the majority of instances are the reviewers'. The combination, we trust, will not prove too unhappy.

Annual Report of the Commonwealth Fund for the Year Ending September 30, 1942. 62 pp.

This 24th annual report of the Commonwealth Fund records a moving story of the efforts made "To do something for the welfare of mankind" in conformity with the declared purpose of the Fund. Disbursements during the year exceeded \$1,937,000 and again the greater part of the available income has gone through various channels into the promotion and conservation of health. Besides making substantial contributions to several war funds, continuing the medical research for which the Fund has long been known, and promoting interest in medical education and in mental health, the Fund once again has made direct investments in public health and health studies. A unique feature lies in the field units of specially trained staff made possible in Tennessee, Mississippi, and Oklahoma to afford a mobile resource which must be of immense tactical value to state health officers in these days.

The Fund has continued grants to rural hospitals and to international fellowships, fifteen of which went to Latin American Fellows last year. Among the books published by the Fund are two of especial interest in public health, *The Modern Attack on Tuberculosis*, by Chadwick and Pope, and *Solving School Health Problems*, by Nyswander. Many a health officer who reads this report will wish that he

were as free to direct his efforts into fruitful channels with long-range promise as the officers of the Fund have been. The public health profession will agree that the hope of the future lies in the kind of strategy which underlies the work described in this report.

REGINALD M. ATWATER

Communicable Diseases—By Nina D. Gage and John Fitch Landon (3rd ed.). Philadelphia: Davis, 1942. 458 pp. Price, \$3.50.

The third edition of *Communicable Diseases* by Gage and Landon carries the same high standards as the first two. There are added sections on tetanus, the differential diagnosis of communicable diseases characterized by exanthematous eruptions, and on the home care of the communicable disease patient. To those who are not familiar with this book it should be stated that there are many appropriate illustrations which in the main are very well done. A few of the color plates could be improved by the natural color processes now available.

The format of the book is excellent. An outline of the subject matter of each section is followed by a discussion of the medical consideration, the methods of control, and the nursing care. This orderly arrangement is helpful when using the book for reference.

The chapter on the sulfonamides has been revised and gives practical information as to the type of the drug to

be used and dosage for the various diseases. Minor misstatements regarding the availability of sulfathiazole in the section on gonorrhea, and regarding the specificity of sulfanilamide in the treatment of gonorrhea in the section on chemotherapy are mentioned by the reviewer but are not of great importance, since the book has been prepared for the primary purpose of instruction in the nursing care of communicable disease.

The section dealing with the Commoner Communicable Diseases, such as diphtheria, scarlet fever, measles, and whooping cough, is well written and gives a particularly clear picture of the clinical as well as nursing aspects of the diseases described.

WILTON L. HALVERSON

Community Workshops for Teachers in the Michigan Community Health Project—*By Henry J. Otto, et al. Ann Arbor: University of Michigan, 1942. 303 pp. Price, \$2.00.*

This book describes a pioneering experiment in organizing and conducting four workshops for in-service training of teachers during the summer of 1941 by the University of Chicago and the University of Michigan, aided by the Kellogg Foundation. The workshops dealt respectively with the following problems: health education; science education; democratic citizenship and the health of children and problems in social science, library science and the language arts.

A unique feature of the plan is the "grass roots" approach which was used. The workshops were conducted in four local communities within a seven county area. Teachers helped determine the problems for attention and had an active part in daily program planning. Emphasis was placed on meeting local needs through more effective use of local resources. Thus the local

health personnel were important resource people in the health education workshop and the local health problems important aspects for study.

Among the activities described are work in the laboratory school, field trips, individualized study, group discussions, and coöperative projects with community groups. Emphasis was placed on the practical application of theoretical concepts in community living. The book is well illustrated.

The growing pains associated with this newer approach are revealed with frank objectivity. The evaluation of the workshops by the teachers themselves shows a gratifying satisfaction with the informal program.

Adaptations of the methods used may be one practical answer to in-service training under present wartime conditions. Local departments of health and education and teacher training institutions should find help in this book on ways in which they can stimulate and assist in similar training programs so that more teachers are made ready to take greater responsibility for school and community health work.

RUTH E. GROUT

Extra-mural Teaching of Preventive Medicine and Public Health—*By Alfred Korach, M.D., with a preface by T. J. LeBlanc, M.D. Medical Bulletin of the University of Cincinnati, Vol. IX, 1942. 143 pp.*

Public health workers, as well as medical educators, have become increasingly concerned with the need for greater emphasis in the medical school curriculum upon the prevention of illness and upon the influence of social, economic and other environmental factors in the occurrence of disease. It has also been recognized that the undergraduate medical student should be made familiar with the community health resources which assist and supplement the efforts of the private prac-

itioner in the treatment and prevention of disease. It is with these phases of medical education that this volume deals. Particular attention is given to field instruction which the authors consider as the *Extra-Mural Teaching of Preventive Medicine and Public Health*.

No claim is made that the program of teaching in the Department of Preventive Medicine of the University of Cincinnati College of Medicine is the best or only way to approach the problem. In fact, the extensive outline and analysis of the required and elective course of instruction for sophomore medical students followed since 1939 is offered as a guide and a source of reference for others faced with the task of planning curricula with similar aims. Dr. LeBlanc and Dr. Korach are to be commended for their presentation. Ample space is devoted to student comments upon this experience and a valuable bibliography of authoritative references is appended to the text.

T. D. DUBLIN

Hospital Discharge Study—Hospitals and Hospital Patients in New York City (Vol. I)—By Neva R. Deardorff and Marta Fraenkel. *New York: Welfare Council of New York City*, 1942. 209 pp. Price, \$1.00.

Since Dr. Bolduan first pointed out the importance of collecting hospital morbidity statistics in 1913, a great deal has been written about the problem but few actual reports on the collection of material have appeared. This volume, the first of three, is of importance since it represents the first contribution to this field which includes almost complete data on hospitalization in an urban center for an entire year.

The Welfare Council of New York City, with the assistance of state and city work relief authorities and the WPA, initiated the survey on January 1, 1934. Of a total of 134 hospitals under voluntary and municipal control,

offering general and special service of any kind, and institutions for the chronically ill in New York City (excluding proprietary, federal and state hospitals) 113 hospitals with 88 per cent of the total number of beds participated in the study; 576,623 discharges representing 546,235 persons occurred in these hospitals in 1933.

This first volume contains a summary and description of the general characteristics of these patients including demographic data, and discussions of migration for hospitalization, diagnosis and mortality, financial status, length of stay and readmissions. The text is supplemented with 58 tables and 12 appendices. In addition, there is a carefully selected bibliography on morbidity and methods of measuring morbidity.

The detailed study of diagnosis and morbidity is to be published in the next two volumes. Information of this type, together with material now available through Hospital Service Plans, is needed for adequate and proper planning of future hospitalization.

EDWIN L. CROSBY

The Lives and Loves of Huber the Tuber—By Harry A. Wilmer, M.D. *New York: The National Tuberculosis Association*, 1942. 83 pp. Price, \$1.00.

A riotously gay tale of a tuberculous bacillus and his friends. The entire gang are so personalized as to become real creatures battling against Monosights.

In a most realistic fashion, Huber accompanied by his troops, like Alice falling down the hole to Wonderland, slipped into the bronchial tube to invade the lungs of a human—then the war begins—the gang launching their treacherous work against Monosights. Each stage of the struggle occurring in the lung is graphically described in words as well as in unique illustrations. Few there are so uninformed as to miss

the lesson conveyed throughout the drama.

Lungland becomes a friendly territory attacked by enemies without. All of these characters are identified with whimsical titles suggestive of the day, Rusty the Bloodyvitch, Huey the Long Tuber, Gobbles, Gorrington, Takiotuber. Chief of the Monosights is Corpuscule Lipsky, whose entire army become the Signal Corps, Military Police, Mechanized Forces, Infantry, Engineer Corps, etc.

A brief description in a serious vein is offered with each act and also in a summary presented as a preface. The only weakness in this delightful contribution is the author's failure even to hint at the time element involved. It all seems to happen in a brief period, a day or even an hour. Perhaps that was the author's intention as the period of invalidism required for the success of Monosights requires patience and persistence to endure the enforced rest necessary in combating Huber the Tuber.

Dr. J. Arthur Myers in the introduction to the book gives a glimpse of the remarkable character and unconquerable spirit of the youthful author who wrote and illustrated the book during months of leisure due to a tuberculous bacillus.

"Dr. Wilmer did not become discouraged because of his fate but rather he saw an opportunity to enter into the great campaign against tuberculosis, which otherwise probably would not have presented itself. The tubercle bacillus had suddenly caused a termination of his hospital work; it had seriously interrupted his plans, but almost as though nothing had happened, or as though it had been planned for years, he took up another phase of health work and has pursued it diligently."

This slim volume of 80 pages, with the author's distinctive drawings, is well printed on good paper. The book

can be heartily recommended for old and young. Here's hoping it will become not only a best seller but may be used as the basis for a motion picture.

SALLY LUCAS JEAN

Nutrition and Diet Therapy—By Fairfax T. Prondst (8th ed.). New York: Macmillan, 1942. 1,057 pp. Price, \$3.25.

This edition, published in June, 1942, represents the first revision of this popular book since September, 1938. In a science such as nutrition where scientific research is adding new material at such a rapid rate, it is obvious that a book on this subject needs frequent revision. It is also the obligation of the author to keep the volume of material under reasonable limitation in spite of the new additions being made.

The organization of this edition is practically the same as that of the seventh except that an additional section has been added to include the nutrition and feeding in pregnancy and lactation as well as the feeding of children of different ages. One-fifth of the book is given over to the fundamentals of nutrition, and a little less than 100 pages each to feeding in obstetrics, lactation and children of different ages and to laboratory lessons. The last 600 pages are occupied with Diet Therapy and Recipes. The author well points out that in the hospital the doctor gives the diet orders and the student carries them out. Patients as a rule do not understand the common rules governing nutrition and, therefore, in order to gain their full coöperation it is necessary to explain things to them. The student, consequently, needs training in order to perform these tasks efficiently.

It is to be regretted that the author did not see fit to devote some of the space given to cookery, and other subjects more related to the field of home economics, to such subjects as nutri-

tional field surveys, food rationing, reinforced bread, meat substitutes, and other nutritional matters growing out of federal food supervision as a defense effort.

Nevertheless, the book has proved its value in previous editions and the present one is well up to standard. The author is well known and her presentation of material is extremely practical.

IRA A. MANVILLE

Standard Nomenclature of Disease and Standard Nomenclature of Operations—By Edwin P. Jordon, Editor. Chicago: American Medical Association, 1942. 1,022 pp. Price, \$4.00.

This volume consists of the third edition of the *Standard Nomenclature of Disease* and the first edition of the *Standard Nomenclature of Operations*.

Changes from previous editions of the text on disease nomenclature include: (1) about 3,500 additions, deletions and corrections to individual diagnostic items; (2) the printing in bold face type of some of the more frequently used terms; (3) exclusion of numbers corresponding to those in the *International List of Causes of Death*; (4) the addition of a table of eponymic diseases, and (5) the omission of *Classified* from the original title. The section on operations is an attempt to set up a standard terminology similar in its arrangement and usefulness to the one on diseases.

Despite the wide acceptance of the *Standard Nomenclature* by many well known physicians and prominent hospital groups and its sponsorship by the American Medical Association, many students of nosology and the problems of medical nomenclature question the advisability of its widespread use either in the teaching of standard diagnostic terms or in quantitative medicine as a classification of disease entities. Some of the arguments offered are:

(a) No standardization of diagnostic entities can be agreed on completely without first defining each term and using it only when it both denotes and connotes precisely a meaning understood by all competent physicians. This would be hard enough for the well defined clinical entities, but when attempted for the poorly defined ones, it becomes almost impossible. Standardization also precludes the use of synonyms and eponyms.

(b) The present anatomic and etiological classification is eminently satisfactory for certain diseases, but often becomes quite complicated, particularly in the specialty fields.

(c) The numerical coding system is too complicated to be used satisfactorily either as a diagnostic cross index or as a means for tabulating diseases for statistical purposes. In addition, the time and study necessary to employ the system intelligently is often more than the casual user can afford.

EDWIN L. CROSBY

The Standard of Living in 1860—By Edgar W. Martin. Chicago: Chicago University Press, 1942. 450 pp. Price, \$4.50.

It is the secondary title "American Consumption Levels on the Eve of the Civil War" that best reveals the purpose and content of this interesting source book. Apart from the introductory and concluding chapters, the book consists of eleven topical collections or catalogues of well documented facts which may prove useful to students of economic history, but only inferentially indicate standards of living in the intellectual, ethical, or professional spheres.

There are some 49 tables of costs, consumption, prices, family budgets, wages, population, and similar matters. Documentary footnotes are abundant.

In only one chapter (VIII) of 78 pages is there any information directly

related to health either personal or public, and most of this is dedicated to the quantity and quality of the practice of curative medicine.

No one at all familiar with the scene of medicine or public health will find any facts or ideas in this chapter at all novel in substance or form.

The book will satisfy a curiosity of those who are entertained by turning the pages of a relatively recent past, when there was little notable or inspiring in the American practices of earning and spending and saving and wasting.

This book will probably be found useful as a storehouse of facts. Their interpretation and bearing upon levels of living is not included to a noticeable degree in the text.

The conclusion would seem to have been predictable that the "American Standard of Living" included more goods producible in a mass manner than was the case among Europeans.

The index is well done.

HAVEN EMERSON

Virus Diseases—By Members of the Rockefeller Institute for Medical Research. Ithaca, N. Y.: Cornell University Press, 1943. 170 pp. Price, \$2.00.

This volume is only 170 pp. long and covers certain phases of the virus field. The following six articles constitute the entire work: Virus Diseases with Particular Reference to Vaccinia, Chemical Structure and the Mutation of Viruses, New Hosts as a Key to Progress in Plant Virus Disease Research, Swine Influenza, Human Influenza, and Viruses and Tumors.

Obviously a volume of this size cannot hope to cover the entire field of virus diseases, nor are any pretensions made to do so. The material which is presented is concise and clear-cut. Although dealing with only a small portion of the complicated virus field, the

data have been well digested and to some extent may prove more valuable to workers interested in virology than some of the larger more comprehensive volumes in the same field, which are entirely lacking in critical analyses and offer unselected masses of facts.

Virus Diseases is particularly useful, because the work has been covered by competent specialists in each subject. Working hypotheses have been presented for such fundamental questions as virus immunity and immunization, adaptation of viruses to new hosts, and the course which the infection may take. On several occasions both sides of controversial subjects are discussed.

Virologists and newcomers to the field will find *Virus Diseases* helpful for one reason or another. Although it must be used in conjunction with some of the larger texts in the field it is a necessary and valuable adjunct.

MURRAY SANDERS

War Medicine—A Symposium—Edited by Winfield Scott Pugh, M.D. New York: Philosophical Library, Inc. (15 East 40th St.), 1942. 565 pp. Price, \$7.50.

War Medicine, A Symposium is a collection of outstanding articles on military medicine, orderly arranged and on the whole fairly well illustrated. The articles are grouped under three sections of surgery, aviation and naval medicine, and general medicine. For the most part various articles by English and American authors are quoted entirely or abstracted and the material is concise and factual.

Surgery reviews such subject matter as war wounds and wound healing, burns, anaerobic infections, wounds of the chest, gunshot wounds and their treatment, blast and concussion injuries, shock, blood substitutes and fractures.

Aviation medicine presents certain medical principles peculiar to aviation.

such as hypotension, problems in cardiology, fatigue, compression injuries and the medical aspects of deep sea diving.

General medicine discusses gas casualties, nutrition, allergy, dysentery, certain parasites and certain problems in psychiatry peculiar to military personnel.

Despite the unusual prominence of the contributors to this book the reader gets a series of opinions and recommendations by experts, some of which appear rather extreme to one not experienced in the particular field, and does not get a good descriptive presentation of a single subject followed by specific directions for therapy. Except for this one criticism, *War Medicine* is a book which deserves study by physicians engaged in military medicine and civilian physicians in private practice who expect to enter the service.

L. R. CHANDLER

Publicity—How to Plan, Produce and Place It—By Herbert M. Baus. *New York: Harper, 1942. 252 pp. Price, \$3.00.*

Until recently publicity was synonymous with ballyhoo, "hot air," and the tricky showmanship of P. T. Barnum. Today, however, publicity has divorced itself from its early connotations and has emerged to fill an increasingly important rôle in world affairs. It is still, of course, put to devious uses. When concocted by thwarted dictators, it can help to plunge nations into war; when fashioned and directed by those with humanitarian instincts, it can play a major rôle in molding a new era of peace and progress. Only through an understanding of this subject can we make sure that publicity fulfils its true purpose: to inform the public truthfully, to stir people to think, to encourage the free exchange of ideas basic in a democracy.

It is fortunate, therefore, to have an

authoritative book on publicity appear at this time. Mr. Baus possesses an encyclopedic knowledge of the subject and its ramifications. In a friendly, entertaining, and informative manner the author discusses all types of publicity—its functions, its technics, its operations, and some of the tricks of the craft. The text is split in three main sections: (1) planning or blueprinting, (2) production or manufacture, (3) placement or distribution. The reader is guided through the "beehive complexity" of the daily newspaper office, the news and photo syndicates, and other publicity producing centers. The policies, the do's and don't's and the idiosyncrasies of the editorial craft are also exposed.

The scope of the book is not limited to printed media, but the radio, the motion picture, letters, exhibits, word-of-mouth publicity (telephone conversations and public speeches), parades and pageants, are also included.

The book does not treat of health publicity as such, although the formulas unfolded in its pages can be adapted to the work of the health educator. Mr. Baus briefly discusses sociological publicity—under which health agency publicity might well be included—and he states that publicity emanating from welfare organizations should have quick entree to all publicity media because of its unselfish and non-commercial nature. The author frankly states that the one drawback preventing greater coverage or acceptance of sociological publicity is its dry and uninteresting nature. Mr. Baus warns against "ballyhooing" publicity of this type and suggests that sincerity be the keynote of public agency releases.

As to the qualifications which a publicist should possess, the author states that there are no cut and dried requirements, no specific professional qualifications. The publicist in any field must be a writer-artist-politician-businessman combined. He must know a little about

everything. Perhaps the prime requisite for a publicist is imagination: he must be able to ferret out newsworthy items in material that others would consider only a pile of dull data.

This book is unreservedly recommended—especially to health educators. The writing is lively, the contents are copious, the point of view is sane. Even if one is wholly uninterested in the mechanics of publicity, this book is entertaining as pure reading matter. It should set the feet of any aspirant with a grain of publicity sense along the right path.

JOHN LENTZ

Terminology and Definitions of Speech Defects—By Mardel Ogilvie. *New York: Bureau of Publications, Teachers College, 1942.* 312 pp. Price, \$3.50.

This is an attempt to clarify the matter of terminology of speech defects, but the volume is so overorganized that it is next to impossible to find anything in it.

LETITIA RAUBICHECK

Minerals in Nutrition—By Zolton T. Wirtschafter, M.D. *New York: Reinhold Publishing Corporation, 1942.* 175 pp. Price, \$1.75.

The author discusses the physiological significance of the essential inorganic elements in non-technical language and without consideration of the other essential nutrients. There are inevitable shortcomings in a book which attempts to present the metabolic functions of a single class of nutrients without consideration of the many organic nutrients. The lay reader cannot be accurately informed and gain a comprehension of either physiology or nutrition from this discussion of a single group of elements or compounds.

There are many inaccurate statements. On page 32 it is stated: "Sodium chloride has two vital functions: (1) It helps to maintain the acid-base balance of the body; that is,

it automatically keeps us 'on the alkaline side.' " Carbonate, bicarbonate, and phosphate ions are not mentioned as buffer substances. On page 131 it is stated: "By reducing the manganese content of the diet for rats egg formation fails to occur and reproduction is therefore impossible." On page 118 it is stated: "In cases of goiter, about three times the normal amount of iodine is present in the urine."

The book suffers from an attempt at over-simplification of a complex subject, as well as from careless and inaccurate statements.

E. V. MCCOLLUM

Julius Rosenwald Fund—Review for the Two-Year Period 1940-1942—By Edwin R. Embree, President of The Fund. *Chicago, Ill., 1942.* 39 pp.

This is a stimulating review of the work of The Fund during the past 15 years, in which Negro health occupied a substantial part. This part of the program officially ended in 1942 after the expenditure of a total of \$1,478,000. An excellent condensed report of trends in Negro health is included. The chapter on Color and Democracy shows the underlying significance of the effort to improve medical care, public health, and education for this part of our population.

When Doctors Are Rationed—By Dwight Anderson and Margaret Baylous. *New York: Coward-McCann, 1942.* 255 pp. Price, \$2.00.

The intent of this volume is excellent, namely, to give the general public an insight into the problem of providing medical care and the procedures established to provide adequate medical service for both the military forces and the civilian population. The book succeeds in doing this, however, only moderately well and with uneven balance.

When it describes the procurement

and assignment of physicians from the purely mechanical standpoint, it does so in simple and informative style. When other more difficult and perhaps more subtle problems of medical care are reviewed, the attempt at popularizing leads to a simplification of statement which becomes almost annoying and which results, too often, in the avoidance of real issues.

The authors of any volume designed to popularize somewhat complicated features of nation-wide controversial issues run the risk of inaccuracy in undue popularization. This is particularly true in the chapter dealing with public health, where the comparisons of accomplishment in this country with that of European countries is unfortunately overenthusiastic in favor of our own. After all, Europe and particularly England and Germany have had a long and sound accomplishment in public health. It is different from ours, but need not be too severely disparaged.

The chapter dealing with "Doctors and Boom Towns" shows some confusion between the necessity for providing physicians for industry and that of providing physicians for the areas surrounding industries. In the first instance, the doctors are needed within industry for industrial hygiene purposes, in the second instance, they are required for the general medical care of the surrounding population in civilian life. The two purposes are largely confused in this chapter, with the latter aspect given little or no discussion.

This confusion would not be nearly so serious if it did not result in avoiding entirely the important problem of civilian medical care in a number of boom areas, such as Mobile, Hampton Roads, Valparaiso, San Diego, etc.

In similar fashion the chapter on "Women Doctors in Wartime" hardly does justice to this problem. The 4½ pages devoted to this subject really

leads nowhere with respect to more effective use of women doctors in or outside of the military services.

Much useful information known to the medical profession, but unfamiliar to the layman, is set forth most of the time with clarity and realism. Perhaps the outstanding deficiency of the volume is that it does not recognize any of the problems in medical care which still confront the general public, namely, of distribution of physicians, of the economics of medical care, and of the pressing controversies as to group practice and hospitalization. The discerning public will probably note and assay these omissions in the volume when it is read.

ABEL WOLMAN

Nutrition and the War — By Geoffrey Bourne, D.Sc. (2nd ed.) Cambridge: University Press. New York: Macmillan, 1942. 148 pp. Price, \$1.50.

This short, concise text is designed solely for the layman, and intended as an aid to the housewife in the selection of alternative foods in the event that the usual foods were unobtainable. In easily understandable language, it considers the energy value of foods, treats of the function of proteins, fats, and carbohydrates, lists the common or well known vitamins, and considers each one separately as to its significance.

Under the chapter headed "Nutrition and War Time," the question of protective and non-protective foods is considered as well as vitamin overdosage, food supplies, food and health, in addition to a short treatise on the German and Russian food situation. The figures quoted for overdosage of vitamins A and D are somewhat out of line, and much more conservative than commonly accepted. Finally, the author in this chapter postulates the problem of the nutrition of the future. The last chapter in the text, consisting of nearly one-half the entire volume,

deals with the nature and composition of various foodstuffs, listing caloric value, protein, fat, carbohydrate, mineral, and vitamin content in terms of very good, good, fair, very poor to negligible.

HENRY T. SCOTT

Group Differences in Urban Fertility—By Clyde V. Kiser. *Baltimore: Williams & Wilkins, 1942. 284 pp. Price, \$2.50.*

Group Differences in Urban Fertility is an analysis of the fertility data obtained in the National Health Survey in 1935-1936. The character and size of the sample population studied make this a reliable source of information, even though the data are not derived from the whole of the United States. Until the detailed 1940 census tabulations are available, Mr. Kiser's study constitutes the most extensive and detailed source of information on recent fertility differentials.

The basic data are in the form of annual birth rates and so are not directly comparable with some earlier studies dealing with the total number of children ever born. Certain conclusions concerning trends in the differentials can be drawn from the material however. In general, the familiar pattern of high birth rates in families of low socio-economic status and increasingly lower birth rates as socio-economic status improved, is repeated in the National Health Survey data. All differentials, however, appeared to be narrowing perceptibly, and in some instances there was a definite reversal of the pattern.

One of the most valuable chapters in the book deals with the cross-classification of the attributes considered. For example, the birthrates of native white wives, classified according to occupational status of the husband, were analyzed for the effects of income and education within each occupational group. This analysis demonstrates

clearly the biases in each single type of classification. The chapter on pregnancy wastage, though based on fragmentary data, should be of special interest to public health workers.

The book will be valuable as a reference text embodying detailed analysis of the most recent broad population data for selected cities of the United States.

REGINE K. STIX

Proceedings of Sixty-Ninth National Conference of Social Work, New Orleans, May, 1942—*New York: Columbia University Press, 1942. 670 pp. Price, \$5.00.*

Wartime problems held the center of the stage at the 1942 National Conference of Social Work.

Reviewing the Conference proceedings, recently off the press, we see this unifying theme tying together much more effectively than usual, this great conference, so likely to resemble a six ring circus in its wide range of interests and activities.

Malcolm MacDonald, High Commissioner from the United Kingdom of Canada, perhaps came as near sounding the keynote of the conference as any of the notables on the program. Said MacDonald, "One of the best ways of preserving the morale of the civilian population is by keeping at full blast all those social services which can contribute to a fitness of body and a calmness of mind under a terrific ordeal."

An excellent group of papers is found in this volume: President Shelby Harrison's Social Work on Three Fronts; Vera Micheles Dean on After Victory; a series of thoughtful discussions of the upsurging Negro problem in the South; others on the impact of war on social work needs and on children; developments in the fields of health, employment, and Social Security. Together they constitute a volume that is timely as well as a valuable permanent record.

BLEECKER MARQUETTE

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

War's Toll—Though the death rate in this representative sample was lower for 1942 than for 1941, most of the improvement occurred in the childhood age groups and over age 55. Among white males ages 20 to 24 the excess was almost 34 per cent. Nearly half these deaths were in the military personnel. This is a solemn reminder of what we may expect of the current year.

ANON. Mortality Record for 1942. Stat. Bull. (Met. Life Ins. Co.), 24, 1:1 (Jan.), 1943.

First Aider—Stop, Look, Listen!—External heat to treat shock is a time-honored method. Anyone who has read even the most elementary first aid manual knows enough to run for blankets and not-too-hot water bottles. Cautiously, it is proposed that heat be *not* applied in shock when only the skin is cold but rectal temperature is normal or above. The chief reason for including a reference to the subject still in the research stage in this column for practising health officials is to remind us that humility is above price, and that even in matters of first aid the last word is yet to be said.

ANON. Cooling in Shock (An Editorial). J.A.M.A. 121, 6:432 (Feb. 6), 1943.

Brucella suis—Here is still another for the record: an epidemic of brucellosis numbered 77 victims among the users of an unpasteurized milk supply. Raw milk addicts may be reminded that the average duration of fever was 6 to 8 weeks, and that undulant fever is no fun.

BORTS, J. H., *et al.* A Milk-Borne Epidemic of Brucellosis. J.A.M.A. 121, 5:319 (Jan. 30), 1943.

What the Division of Industrial Hygiene Does—Old men, women, the handicapped, and veritable youngsters are being taken into industry. And these people who lack physical adaptability and experienced work-habits of the men who have gone into service, are laboring harder and for longer hours than heretofore. That is a challenging introduction to the present-day industrial hygiene program if ever there was one.

DRAPER, W. F. Government's Obligation in Industrial Health. New Eng. J. Med. 228, 6:178 (Feb. 11), 1943.

Department of Intimate Confidences—Knowing next to nothing about psychology it's not for the likes of me to pass judgment, but this paper on current edition parent-child relationships strikes me as so eminently sound that it is commended heartily to you—parent, if you are one. When I reached "never is a parent to strike his child *except* in anger" then I just knew this item must appear. P.S. There are many solid looking papers in the same issue that I didn't read, but you should.

GILDEA, M. C.-L. The Modern American Parent. Ment. Hyg. 27, 1:43 (Jan.), 1943.

Health Educators Will Agree—First objective in a national health program is to intensify public health education: this is truer today than ever before. Next in order of importance is nutrition to which is linked child health. The "also ran" activities constitute a long list in this Canadian Health Officer's outline of present-day health administrative problems.

GROULX, A. A National Health Program. *Canad. J. Pub. Health* 34, 1:10 (Jan.), 1943.

Despite Theoretical Objections—Under as nearly identical conditions as could be obtained in industrial practice, one group of workers was given a vitamin-mineral concentrate, a similar group served as a check. The treated group not only had a greater average production than the controls, but more significant, after the second week, there was a steady increase in rate of production among the treated employees. The discussion of the limitations of research of this character should be read by all would-be researchers.

HAGGARD, H. W. Supplementary Feeding in Industry. *J. Indust. Hyg. & Toxicol.* 24, 10: 332 (Dec.), 1942.

Arthropod-borne Virus Encephalitis—Eastern and western equine, and St. Louis type encephalitis should be classified as a group. The place names bear no relation to the limits of these infections. The rôle of mosquitoes as vectors seems to be established. Mosquito bite protection, larva control, and vaccines all may play a part in prevention.

HAMMON, W. McD. Encephalitis. *J.A.M.A.* 121, 8:560 (Feb. 20), 1943.

Blissless Ignorance —Food for health educator's thought: among a group of cancer patients only 26 per cent had read anything really educative about cancer (and that mostly in the newspapers), only 1.2 per cent had seen a cancer pamphlet and heard a lecture on cancer. They waited on the average $3\frac{3}{4}$ months after the beginning signs before seeking medical help. Conclude the authors: "this educational program is still inadequate and ineffective."

HARMS, C. R., *et al.* Delay in the Treatment of Cancer. *J.A.M.A.* 121, 5:335 (Jan. 30), 1943.

Sanitary (?) Bubblers —A high proportion of drinking fountains now in use would be condemned by any criterion of sanitary decency, and certain types are potentially more dangerous than the old chained tin cup. There's a challenging statement for you, so read all of this brief report.

HITCHENS, A. P., and ROSS, O. A. Bubbling Drinking Fountains. *J. Am. Water Works Assn.* 35, 2:165 (Feb.), 1943.

Epidemiologic Study of Venereal Disease Sources—Evidence to prove what all health workers know to be the case: when prostitution is "regulated" venereal infection rates rise. When it is repressed, they fall. This is an instructive case history of two cities near an army camp.

JOHNSON, B., JR. When Brothels Close, V. D. Rates Go Down. *J. Soc. Hyg.* 28, 9: 525 (Dec.), 1942.

How Our Half Lives—It's about time someone looked into the dietary habits of the favored few. This study of the meals of a considerable group of persons from the upper income level reveals that their diets are markedly deficient in thiamin and riboflavin, only fats were furnished in excess of needs. Milk, eggs, fruit, and whole grain (or enriched) products were frequently found lacking, as they are "on the other side of the tracks." Among the 9 physicians in the group the diets were as bad as the others.

KELLY, H. T., and SHEPPARD, M. A Dietary Study of Subjects from Upper Income Groups. *New Eng. J. Med.* 228, 4:118 (Jan. 28), 1943.

Rural Obstetrics—In that favored region, the first rural area to have a home delivery nursing service, the nurse saw the mother only after the birth certificate was issued in more than half of all cases. This is only one finding of a useful questionnaire study of obstetric care.

O'BRIEN, H. R. Factors in Obstetric Care. New York State J. Med. 43, 3:236 (Feb. 1), 1943.

U. S. P. H. S. vs. Wartime T. B.— Chest x-rays of war workers with the service extended to families of those found positive; follow-up of rejected recruits; reorganization of local programs to meet wartime needs—these are some of the promising objectives of the Office of Tuberculosis Control.

PARRAN, T. Tuberculosis Control Program

of the U. S. Public Health Service. J.A.M.A. 121, 7:520 (Feb.), 1943.

Commonest Pneumonia Types—

In a two year nation-wide sampling, three quarters of all pneumococcic pneumonias were found to be due to ten types of pneumococci. This suggests a revision and simplification of current pneumonia typing procedures.

RUMREICH, A: S., *et al.* A Nation-wide Study of the Bacterial Etiology of the Pneumonias. Pub. Health Rep. 58, 4:121 (Jan. 22), 1943.

ASSOCIATION NEWS

THREE-DAY WARTIME PUBLIC HEALTH CONFERENCE AND SEVENTY-SECOND ANNUAL BUSINESS MEETING

AMERICAN PUBLIC HEALTH ASSOCIATION

New York, N. Y., October 12, 13, 14, 1943

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- P. J. Paul L'Heureux, M.D., D.P.H., 319 Dumoulin St., St. Boniface, Manitoba, Can., Medical Director, City of St. Boniface
Jack Masur, M.D., Dupont Circle Apts., Washington, D. C., Medical Division, Office of Civilian Defense, P. A. Surgeon, U. S. Public Health Service (R)
Frank L. McGahey, M.D., Health Dept., Grenada, Miss., Director, Grenada County Health Dept.
Milton B. Sherrard, M.D., North Central District Health Unit, Lewiston, Ida., Acting Director
Francis M. Teeple, M.D., Court House, Fremont, Ohio, Health Commissioner, Sandusky County District Board of Health
Russell H. Wilson, M.D., 2801 6th St., Bremerton, Wash., Director, Dept. of Public Health
R. Murray Wingard, M.D., Wilkinson County Health Dept., Woodville, Miss., Director
Preston E. Wright, M.D., 325 W. Broadway, Anadarko, Okla., Director, Caddo County Health Dept.
Firman M. Wurtsbaugh, 21 S. Franklin St., Richwood, Ohio, Health Commissioner, Union County General Health Dist.

Laboratory Section

- Alfred P. V. Auersperg, M.D., 206 Rosa Rd., Schenectady, N. Y., Bacteriologist, Ellis Hospital Laboratory
Chester W. Christensen, Ph.D., 920 Henry St., Detroit, Mich., Bacteriologist, Difco Laboratories, Inc.

- Albert E. Edel, Ph.D., 10 Hill St., Newark, N. J., County Toxicologist, Chief Medical Examiners Office, Essex County
Max Feldman, Ph.M., U. S. Naval Air Station, Georgetown, British Guiana, Laboratory Technician
Wayne A. Geib, M.D., Fitzsimons General Hospital, S. M. D. T., Denver, Colo., Instructor, Laboratory Section
Louis S. Grant, M.B., M.P.H., Government Bacteriological Laboratory, North St., Kingston, Jamaica, B.W.I., Medical Health Officer, Government Medical Service
Harry E. Morton, Sc.D., Univ. of Pa., Dept. of Bact., School of Medicine, Philadelphia, Pa., Associate Professor in Bacteriology
Paul E. Portner, 16 W. Market St., Marietta, Pa., Chief Chemist, Gilliland Laboratories, Inc.
Carolyn Roth, 5636 Oakridge Ave., Jacksonville, Fla., Research Serologist, State Board of Health
Henry W. Schoenlein, M.S., 920 Henry St., Detroit, Mich., Asst. Director, Dept. of Bact., Difco Laboratories, Inc.
W. French Skinner, C.P.H., State Dept. of Agriculture, Laboratory, Richmond, Va., Senior Scientist
W. Basil Thompson, M.D., Lederle Laboratories, 30 Rockefeller Plaza, New York, N. Y., Division of Medical Education

Vital Statistics Section

- J. Evelyn Brown, 1344 Victoria Ave., Victoria, B. C., Can., Statistician, Dept. of Vital Statistics, B. C. Government

Engineering Section

- Eugene J. Cadle, Box 516, Logan, W. Va., Sanitarian, State Health Dept.
- Sol H. Goldstone, M.S., 1987 Indiantale, Detroit, Mich., Defense Sanitary Chemist, Mich. Council of Defense and Detroit Water Supply Dept.
- Arthur J. Harvey, 237 Granite St., Cadillac, Mich., Sanitarian, Wexford County Health Unit
- Donald D. Rushey, 411 Herald Bldg., Syracuse, N. Y., Junior Sanitary Engineer, New York State Dept. of Health
- Charles J. Sheetz, 1409 N. Quincy, Topeka, Kans., Engineer and Director Division Sanitation, Topeka City-Shawnee County Health Dept.
- Arthur Wallach, 411 Herald Bldg., Syracuse, N. Y., Junior Public Health Engineer, U. S. Public Health Service
- Milford A. Welsh, 15 Bank of Commerce Bldg., Prince Albert, Sask., Can., District Sanitary Officer, Dept. of Public Health

Industrial Hygiene Section

- Garnet R. Coss, R.N., Wheeling Steel Corp., Wheeling Factory, Wheeling, W. Va., Head Nurse
- Harold Earnheart, M. D., Swift and Company, Union Stock Yards, Chicago, Ill., Medical Director
- Lieut. Walter H. Konetzko, Arsenal Operations Dept., Bldg. 43, Edgewood Arsenal, Md., Asst. Industrial Hygiene Officer, Chemical Warfare Center
- Frank E. Macaulay, 1415 Mott, Saginaw, Mich., Industrial Hygiene Engineer, State Dept. of Health
- Lieut. Jack Mayer, Arsenal Operations Dept., Bldg. 43, Edgewood Arsenal, Md., Chemical Warfare Service, Industrial Hygiene Division
- William A. McQuary, 1701 North Polk, Little Rock, Ark., Asso. Chemist, Division of Industrial Hygiene, U. S. Public Health Service
- Raymond C. Sunderman, M.D., 4938 Labadie, St. Louis, Mo., Medical Director, U. S. Cartridge Co.

Food and Nutrition Section

- Mary S. Feth, State Health Dept. 711, Santa Fe, N. M., State Nutrition Consultant, State Dept. of Public Health
- John L. Heid, Box 83, Winterhaven, Fla., Senior Chemist in charge, U. S. Citrus Products Station
- Milla E. Newland, M.S., 348 College St., Burlington, Vt., Nutrition Consultant, State Dept. of Public Health
- Benjamin F. Sieve, M.D., 371 Commonwealth Ave., Boston, Mass., Practising Physician

Maternal and Child Health Section

- Edythe G. James, R.N., 130 Hazelmere Rd., New Britain, Conn., Staff Nurse, State Bureau of Child Hygiene
- Eva Landsberg, M.D., 925 West End Ave., New York, N. Y., Acting Asst. Health Officer, Dept. of Health, City of New York

Public Health Education Section

- C. Marie Beede, Keene Valley, N. Y., Exec. Secy., Essex County Tuberculosis and Public Health Assn.
- Helen C. Brennan, M.A., 4020 Market St., Amsterdam, N. Y., Exec. Secy., Health Adviser, Montgomery County Tuberculosis and Health Assn.
- Stephen S. Brown, M.D., 22 Arsenal St., Portland, Me., Director of Maine General Hospital
- William A. Ettel, 125 Worth St., Bureau of Health Education, New York, N. Y., Senior Administrative Asst., Dept. of Health, City of New York
- Dorothy M. Kenyon, 23 Lexington Ave., New York, N. Y., Graduate Student, Brooklyn Visiting Nurse Assn.
- Bee H. McKerracher, Strathcona Hospital, Range Rd., Ottawa, Ont., Can., Asst. Superintendent and Instructor of Nurses
- Forrest Nelson, 837-A S. Fifth St., Springfield, Ill., Librarian, State Dept. of Public Health
- Margaret T. Norton, 89 Pondfield Rd., Bronxville, N. Y., Exec. Secy., Westchester Cancer Committee.
- Herbert Ratner, M.D., 1018 N. Harlem, River Forest, Ill., Director of Student Health, Loyola Univ.
- Edward R. Reinig, M.A., 3735 Fourth, Detroit, Mich., Health Educator, State Dept. of Health
- Simon Shapiro, D.D.S., 142 Joralemon St., Brooklyn, N. Y., Member, Advisory Committee, Committee on Neighborhood Health Development
- Austin E. Smith, M.D., C.M., 5723 Kimbark Ave., Chicago, Ill., Secy., Council Pharmacy and Chemistry, A.M.A.

Public Health Nursing Section

- Marion C. Bakken, 521 Idaho St., Boise, Ida., Orthopedic Field Nurse, State Dept. of Health
- Marie Chard, 502 S. Eye St., 7, Tacoma, Wash., Advisory Public Health Nurse in Maternal and Child Health, Washington State Dept. of Health
- Mary E. Dyer, Box 512, Laramie, Wyo., County Public Health Nurse, State Dept. of Public Health Nursing
- Bertha M. Henderson, R.N., 9 N. Ontario St.,

- Toledo, Ohio, Coördinating Director of Nurses, Toledo Dept. of Health
- Dagmar H. Johnson, 1020 Beltrami, Bemidji, Minn., Advisory Nurse, Dist. Health Unit No. 1, State Health Dept.
- Eardie C. Kauffman, 422 N. Main St., Pleasantville, N. J., Supervising Nurse, American Red Cross, Atlantic County
- Elizabeth J. Mackenzie, 300 West York St., Norfolk, Va., Director Public Health Nursing Service, City Union of The King's Daughters
- Katherine MacKenzie, R.N., 132 Main St., E., North Bay, Ont., Can., Public Health Nurse, Dept. of Public Health, North Bay, Ont., Can.
- Dorothy Millington, 99 Pleasant St., Ayer, Mass., Public Health Nurse, Ayer Board of Health
- Eloise T. Phelps, 7235 Constance Ave., Chicago, Ill., Supt. of Nurses, Chicago Health Dept.
- Marion M. Redmond, M.P.H., 570 Howard Ave., New Haven, Conn., Director, Bureau of Nursing, Dept. of Health, New Haven, Conn.
- Mamie A. Seibert, R.N., Davis-Fairfax Community Nursing Assn., Davis, W. Va., Community Nurse
- Helen M. Smith, R.N., P. O. Box 505, Perth, Ontario, Can., Public Health Nurse, Ontario Dept. of Health
- Alma M. Talley, R.N., 4518 West Seminary, Richmond, Va., Supervisor, Instructive Visiting Nurses Assn.
- Lola H. Torbert, 17 S. Downing, Denver, Colo., Nurse, Denver Tuberculosis Society
- Romayne Wicks, R.N., 1014 Evergreen Ave., Goldsboro, N. C., Public Health Nurse, Venereal Disease Control, Wayne County Health Dept.

Epidemiology Section

- William B. Bailey, M.D., 227 Kirk St., Morgantown, W. Va., Health Officer, Monongalia County Health Dept., U. S. Public Health Service, P. A. Surgeon (R)
- Joseph C. Bender, Ph.M., 9 De Forest Ave., Summit, N. J., Dept. of Epidemiology, Naval Medical Center, Bethesda, Md.
- Joyce E. Blunt, Division of Vital Statistics,

- Parliament Bldg., Victoria, B. C., Can., Statistician, Provincial Board of Health
- Lieut. Stephen A. Ginn, M.C., Epidemiological Unit, Naval Operating Base., Norfolk, Va., Medical Officer, U. S. Navy

Unaffiliated

- A. H. Christiansen, Veterans Administration, Boise, Ida., President, Idaho Public Health Assn.
- Morton C. Creditor, Biology Dept., Purdue Univ., Lafayette, Ind., Graduate Asst. in Bacteriology
- David M. Dorin, Beth Israel Hospital, Stuyvesant Park, East, New York, N. Y., Asst. Director
- Major Harold B. Hilton, M.A.C., Headquarters First Air Force, Mitchell Field, N. Y., Administrative Asst. to Surgeon
- Gloria A. Kay, 14 Clinton St., Cambridge, Mass., Research Assistant at Thorndike Memorial Laboratories
- Albert G. Milbank, LL.B., 15 Broad St., New York, N. Y., President of Milbank Memorial Fund
- Frederick A. O. Schwarz, LL.B., 15 Broad St., New York, N. Y.
- Hilda A. Weidner, R. N., 122 N. 18th St., Warwood, Wheeling, W. Va., Charge of First Aid, Wheeling Steel Corp.

DECEASED MEMBERS

- Richard P. Borden, Fall River, Mass., Elected Member 1920, Unaffiliated
- Clarence N. Boynton, Phoenix, Ariz., Elected Member 1916, Elected Fellow 1935, Laboratory Section
- Thomas E. Camper, M.D., Corunna, Mich., Elected Member 1936, Health Officers Section
- Marvin F. Haygood, M.D., West Point, Ga., Elected Member 1918, Elected Fellow 1938, Health Officers Section
- Theodore F. Pappe, Buffalo, N. Y., Elected Member 1940, Food and Nutrition Section
- J. F. X. Staek, M.D., Hoboken, N. J., Elected Member 1923, Health Officers Section
- Frank A. Williams, M.D., Lake Providence, La., Elected Member 1936, Health Officers Section

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

POSITIONS AVAILABLE

U. S. CIVIL SERVICE COMMISSION. Public Health Nursing Consultants, 5 grades. Write U. S. Public Health Service, Washington, D. C.

Physician, man or woman, as director of Division of Maternal, Child and School Hygiene in southern city department of health. Woman physician with pediatric training preferred, public health experience not essential. To operate prenatal, infant and preschool clinics and promote school health program. Salary commensurate with ability and qualifications of applicant. Apply Box J, Employment Service, A.P.H.A.

Southern state department of health seeks several obstetric and pediatric consultants, requiring a minimum of a year's residency in a specialty, immunity to draft and preferably training in public health. Men and women are eligible. Salary \$300 per month plus travel. Apply Box C, Employment Service, A.P.H.A.

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, medical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tenn., or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

Public Health nurses wanted for two-county unit in Michigan. Must be graduates with a minimum of 4 months' public health training or 8 months' training under supervision. Salary \$1,800 per year

with travel allowance \$35 to \$41 per month. Must drive and own a car. Address Dr. Koupal, Director, Alger-Schoolcraft Health Dept., Manistique, Mich.

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sanatoria. Open competitive examinations will be held and the resulting lists are expected to be in existence for 2 years or longer. Residence requirements are waived for professional positions.

INDUSTRIAL HYGIENISTS

The Research Section of the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md., needs chemists, physicists, and medical technicians, as well as laboratory assistants in these fields. There is also opportunity for persons without college education, specific training or experience who are interested in such positions. Women now form one-third of the employees in the Research Section.

Wanted: School Dental Supervisor to administer and operate dental program in City schools and clinics in City 50,000 population. Salary \$3,000 to \$3,600 with travel allowance. Those interested should address Dr. W. A. Browne, City Health Department, Alexandria, Va.

Wanted: Chemist and Bacteriologist experienced in the food field for position

as director of laboratory operated by national association. Preference given to man familiar with soft drink industry and capable of addressing meetings and writing for publication. Apply in writing giving brief history, references, salary, and draft status. Address American Bottlers of Carbonated Beverages, 1128 Sixteenth St., N.W., Washington, D. C.

The Milwaukee City Service Commission announces an examination for assistant chief in charge of sanitary inspection. Salary first year \$210 per month increasing by \$10 increments annually until a maximum of \$260 per month is reached. Applicants must be citizens of the United States, between 25 and 45 years of age. Those interested may communicate with the Milwaukee City Service Commission, Room 716, City Hall, Milwaukee, Wis.

Sanitarian wanted in county of 28,000 in Midwest. Salary \$1,800 plus \$500 travel. Must own car. Complete supervision and execution of sanitation program, including milk, water, food-handling, etc., and general sanitation of

environment in county. Address Box I, Employment Service, A.P.H.A.

Merit System for Personnel Administration, Delaware, is accepting applications for position of Deputy State Health Officer in Delaware State Board of Health. Salary range \$3,600 to \$4,200. Applications accepted until further notice. Those interested should communicate with Merit System Supervisor, P. O. Box 1911, Wilmington Delaware, or State Board of Health, Dover, Del.

The Board of Health, Territory of Hawaii, announces applications will be received for positions as Medical Technician in their public health laboratories. The positions: Civil Service Classifications, SP-5, salary range \$154.17 to \$192.92 per month; SP-6, \$172.50 to \$217.50 per month, subject to retirement deductions under Hawaiian Civil Service System, plus graded bonus for the period of time such bonus remains in effect for Territorial Government employees.

Interested persons may make written application to Board of Health, Territory of Hawaii, P. O. Box 3378, Honolulu, T. H.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK, N. Y.

In view of the current active demand for trained and experienced persons in public health it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

M.D., Dr.P.H., interested mental and industrial hygiene, chief of mental hygiene clinic, on staff of psychiatric hospital, speaker, writer, author of books on health, diplomate in psychiatry, professor of psychiatry. Ineligible for military service because of age, healthy, vigorous, able to work hard, now in private practice; would make sacrifice and accept decent but lower remuneration than present income if he could be employed in war industry, preferably New York, New Jersey, or Connecticut. United States citizen. Had important government job in last war. Speaks and writes several languages. A-504.

Milk sanitarian open for position July

1, 1943. Fifteen years' experience administering and enforcing milk sanitation laws and regulations in midwestern state. References. M-500.

Bacteriologist, 28, Iowa State College, draft immune, 3 years' experience public health laboratory. Experience in investigation and control activities on water, sewage and sanitation, as chemist and bacteriologist and serologist in syphilis and enteric diseases. L-465.

Physician, age 36, M.D. Iowa, Dr.P.H. Harvard, specializing in tuberculosis, seeks position as medical director of a sanatorium or a state bureau of tuberculosis. Exempt from military service. A-476.

NEWS FROM THE FIELD

THE NATIONAL RESOURCES PLANNING BOARD REPORTS

On March 10, President Roosevelt sent to Congress two reports of the National Resources Planning Board. Long anticipated, they had been referred to variously as "blueprints for the future of democracy," "the American Beveridge plan," and "schemes for the complete socialization of the United States." One document, titled "National Resources Development—Report for 1943," dealt with the Board's work on post-war plans and presented a record of wartime planning activities. Temporary measures for the transition period between the cessation of hostilities and the restoration of a peacetime economy are recommended. Guarantees of jobs for everyone able to work and decent living conditions for everyone are part of the long-range planning for peacetime.

The second report on "Security, Work and Relief Policies" was described by the President in his message of transmission to Congress as having been developed over the last three years by the Board in coöperation with the federal agencies concerned and with the help of citizens with special knowledge and competence in this field. "It reviews," he said, "the accomplishments and experience of the last ten years, pointing out some of the weaknesses of our security system, and suggesting ways and means of improving and strengthening the whole program." He expressed the hope that Congress would give full consideration to these matters during this session.

This report contains specific recommendations based on a comprehensive review of the various public measures taken during the last ten years to pro-

vide greater security to the American people. In its introduction, the Board states: "Four main points seem to need emphasis:

"Our economy must provide work for all who are able and willing to work. Included in this is a special responsibility for an adequate youth program which should be an integral part of any Governmental undertaking to establish security. This will be peculiarly true in the postwar period.

"For great numbers whose work is interrupted, the social insurances must carry much of the load of providing adequate income.

"Where the insurance or work policies fail to take care of an interruption in income, adequate guarantees of minimum aid and assistance must be given both to individuals and families through a general public assistance system.

"Where adequate services essential to the health, education, and welfare of the population are not available, public provision should be made for the development of such services.

"But no one of this series of proposals should be expected to solve the problem of insecurity. Taken together, they constitute a rounded and integrated program. Any one of them standing alone can be criticised as inadequate, and properly so. Unfortunately, complete and well rounded programs seldom are able to be adopted at one time. Living is so complicated and our system so intricate that to change it except step by step may create stresses more serious than the evils the program is designed to correct. The program suggested here is not of that kind. It is all within the realm of practical realization."

Governmental responsibility toward many aspects of living is recognized and clearly stated. A policy of public aid is recommended, based upon acceptance of the facts that the need for public aid will be long and persistent; that maladjustments in the national economy and personal physical or psychological

defects, many of which are remediable, cause the need for public aid, and that social problems created by economic insecurity require a series of diversified programs for their solution.

The specific recommendations for extending the social security program include:

Development of a system of social insurance against temporary and permanent disability.

Expansion of the unemployment compensation system to embrace employees of non-profit corporations, agricultural and domestic workers, and employees of small firms.

Increase of the benefits period to 26 weeks.

Reconsideration of benefit formulas so that recipients can maintain themselves without recourse to other forms of public aid. Payment of dependents' allowances "might be a first step in this direction."

Abolish experience rating as a part of the unemployment compensation program.

Replace the present federal-state system with a wholly federal system.

Extend old age and survivors insurance to cover employees of nonprofit corporations, agricultural and domestic workers.

Revise financial arrangements to provide that part of the costs of old age and survivors insurance is drawn from the general tax revenues.

Increase benefits payable to the low-income groups under old age and survivors insurance.

Federal grants-in-aid for general public assistance, in addition to adequate work and social-insurance programs, available on a basis reflecting differences in need and economic and fiscal capacity as between the states.

Access to health education and welfare services for everyone, requiring marked expansion of present services, especially in low-income areas, the responsibility for their development to be shared by local, state, and federal authorities.

Administration of public social services by qualified full-time personnel selected on the basis of merit.

More adequate medical care. The federal government "should stimulate, assist or undertake constructive action to provide such care for the millions whose need cannot be fully met from their own resources."

Adequate provisions for promoting the health of mothers and children.

Expansion through federal aid of state and local child welfare services for the prevention

of neglect and delinquency so that these services will be "everywhere available."

Provision of free school lunches for all school children.

Extension of the stamp plan for the distribution of surplus commodities to the entire low-income population.

The report is definite with regard to the administration of public aid programs. A single agency should administer all public assistance programs operating in one locality. There should be a central information office in every community to inform applicants for aid of public and private community resources and to direct them to the agency best suited to their needs. The merit system, it states, "should be extended upward, downward and outward for all personnel in the field of public aid." Restrictions on residence in a state or a locality as a condition of employment should be removed. Access to all programs offering employment or training should be through public employment offices.

The Federal Security Agency should be given the status of an executive department and the administrator should be given the status of a member of the Cabinet. The agency should be vested with primary and continuing responsibility for promoting and safeguarding the general welfare, health, and education of the people. The establishment of a permanent national advisory body is recommended to study the over-all operation of public aid policies and programs and advise the President, the Congress, and the country. Similar advisory bodies, representing public and private agencies and the public, should be established at the state level. Public agencies should seek to close the gap between administrators and the public by a continued program of public information, by citizen participation in policy-making, and by "more effective use of the coöperation of private welfare agencies which have a necessary

part to play in this enlarged conception of public welfare service."

Recommendations concerning comprehensive federal work programs are included, as well as programs for youth and for the handicapped. "All youth programs," it is stated, "should devote special attention to the physical health of youth, and financial provision should be made accordingly."

No estimates as to costs of the over-all program and its several parts are attempted in the Board's report, although it suggests that the full cost of the public-assistance program should be borne by the general tax payer and the costs of the social insurance program by the workers, employers, and the general tax payers. The Board warns that because it aimed at developing a well coördinated and consistent body of policies and principles, "no one of its specific recommendations can be considered apart from the whole system of which it is an integral part."

WAR CONFERENCE

The medical, surgical, and industrial hygiene experts who are so ably safeguarding the well-being of more than 20 million industrial workers have agreed to pool their knowledge and exchange their experiences regarding the many new and complex problems of today's wartime production. For this purpose their organizations—the American Association of Industrial Physicians and Surgeons, the American Industrial Hygiene Association, and the National Conference of Governmental Hygienists—are combining their annual meetings in a four day "War Conference" at Rochester, N. Y., May 24–27, 1943.

This joint meeting will be a report on the state of the nation, by the men who know, in matters of industrial health. Dr. William A. Sawyer, Medical Director of Eastman Kodak, is General Chairman; Dr. James H. Sterner and Lieut. Comm. J. J. Bloom-

The Chairman of the National Resources Planning Board is Frederic A. Delano.

The report under discussion was prepared by a special committee of the Board under the Chairmanship of William Haber, Professor of Economics, University of Michigan. The agencies, federal and otherwise, represented on the special committee are the Farm Security Administration, Community Chest of Cincinnati, Federal Work Projects, The Catholic University of America, the American Public Welfare Association, the Children's Bureau, and the Federal Security Agency. Eveline M. Burns, Ph.D., was director of research for the study, assisted by Franz Huber, Herman M. Somer, Glen B. McClelland, and a group of economists and research assistants on the staff of the National Resources Planning Board and the various federal agencies concerned with work, security, and relief policies.

field are arranging the programs for the industrial hygienists.

ACTIVITIES OF THE DERMATOSES INVESTIGATION SECTION, U. S. PUBLIC HEALTH SERVICE

The Dermatoses Investigation Section of the National Institute of Health, known as DI, was organized in 1928, under the direction of Louis Schwartz, M.D., medical director, U. S. Public Health Service. The section is concerned with skin disease outbreaks in industry.

Typical of how the DI section operates is the case which arose when an unusual outbreak of skin rash occurred in an eastern war plant. Observers at the plant reported to the DI section's headquarters at the National Institute of Health in Bethesda, Md., that workers making explosives and those filling shell casings were developing a rash on hands, arms, and faces.

DI dermatologists went to the plant and, after a short investigation, found that fumes, generated in the manufacture of TNT, and contact with the powder itself were causing the trouble. With the cause of the outbreaks determined, DI investigators next outlined preventive measures. Detachable sleeves and gloves, that fitted together neatly at the wrists and both made of pliofilm, were developed in the Bethesda laboratory. The flexibility and appearance of this material and its impermeability to the dust, powder, and fumes that were affecting the workers made it the perfect answer.

Safety appliance manufacturers had devised gas masks and work helmets to protect face and head. These sometimes proved awkward and uncomfortable, the doctors reported, and workers discarded them after a few days. Continuing their experiments, the DI researchers produced a pleasant-smelling ointment, for the workers to smear on face and neck, which gave them adequate protection.

An example of the importance of this technical "know-how" is the way DI doctors solved an outbreak of skin trouble among workers in a midwest ordnance plant. The plant reported that men were complaining of skin eruptions on their hands. Plant doctors were puzzled. A DI doctor went to the plant, investigated the manufacturing processes thoroughly, tested all the materials that went into production, all the by-products, all the oils used on machinery and equipment, but he found no clue. Then he examined the workers' clothes and tried to discover some finishing material in their clothing or gloves that might cause the irritation. This line of investigation disclosed nothing. The government dermatologist finally unearthed the fact that the affected workers used a harsh work soap that contained solvents like gasoline and kerosene to remove grease and oil

quickly from the skin. Following the DI doctor's advice, the workers stopped using the harsh cleanser and substituted milder ones suggested by the DI doctors. The rashes cleared up in a short time.

Recently a threatened strike in a Seattle shipyard was averted by prompt action on the part of Public Health Service dermatologists. Electricians in one of the city's four shipyards developed a skin eruption which caused considerable alarm. The workers threatened to strike when they learned they were working with cable made by a copper company where occupational hazards resulting in some deaths had recently been reported. Plant officials persuaded the workers to stay on the job until an investigation could be made. Dr. Schwartz flew to Seattle, examined the workers suffering from the "cable rash," and proved immediately that the cause was the chlorinated compound in which the cable was packed. He recommended that the company use a hood respirator to protect the electricians' faces from the chlorine fumes; that the plant should provide clean overalls every day, and that the workers wear long underwear which they should change daily. These precautionary measures were put into practice at once. The strike was avoided and the workers were protected.

ORGANIZATION OF NATIONAL HEALTH ADVISORY COUNCIL

The Chamber of Commerce of the United States in Washington, D. C., recently announced the formation of a National Health Advisory Council "to project and carry out a broad program looking to health conservation as one of the most important factors in winning the war."

The Council has been organized with James S. McLester, M.D., Professor of Medicine at the University of Alabama, as general chairman. He announced

that the National Health Advisory Council will serve to channel approved technical health information developed by the country's many scientific associations to business organizations and their members throughout the country so that there may be brought about a better public understanding and appreciation of medical science as a means of safeguarding public health to win the war. It will work through the Chamber of Commerce of the United States as a central organization which in turn will use its membership of trade associations, chambers of commerce, and other firms. The Council at the outset is organized with 30 national leaders in medical and health work. It is expected that the membership will be increased.

The Council's first meeting was held in Washington and was presided over by James L. Madden of New York, Vice-President of the Metropolitan Life Insurance Company and Chairman of the National Chamber of Commerce Insurance Department. Participants in the discussion beside Dr. McLester included Wilson G. Smillie, M.D., Cornell University Medical College, New York; Felix J. Underwood, M.D., State Health Officer, Jackson, Miss.; Leverett D. Bristol, M.D., Health Director, American Telephone and Telegraph Company, New York; and H. M. Marvin, M.D., Yale University, New Haven.

Three committees of the Council have been organized under the general chairman which include the following persons:

Community Committee, Chairman Wilson G. Smillie, M.D., New York—Paul White, M.D., J. Burns Amberson, M.D., George Kosmak, M.D., George R. Cowgill, Ph.D., Harry Bakwin, M.D., Ernest L. Stebbins, M.D., F. J. Underwood, M.D., Bailey Burritt, Henry F. Vaughan, Dr.P.H.

Industrial Committee, Chairman Leverett D. Bristol, M.D., New York—Harvey Bartle, M.D., Philip Drinker, Ph.D., Anthony J. Lanza, M.D., John J. Prendergast, M.D.,

Loyal A. Shoudy, M.D., W. A. Sawyer, M.D., Harry E. Ungerleider, M.D., John J. Wittmer, M.D., John Dewey Dorsett, and G. W. Hardy.

Committee on Individual Health, Chairman James E. Paullin, M.D., Atlanta, Ga.—Leroy U. Gardner, M.D., George Morris Piersol, M.D., Russell Wilder, M.D., Alfred Blalock, M.D., Joseph C. Doane, M.D., Marion G. Howell, R.N., Arthur F. Chace, M.D., H. M. Marvin, M.D., Louis Hamman, M.D., Wallace C. Yater, M.D.

PUERTO RICO PUBLIC HEALTH ASSOCIATION

The second annual meeting of the Puerto Rico Public Health Association was held in San Juan at the School of Tropical Medicine and Public Health, January 30-31. The well attended meeting was under the Presidency of Major E. Garrido Morales, M.C., U.S.A., and the following officers were elected:

President—Pablo Morales Otero, M.D.

President-Elect—O. Costra Mandry, M.D.

Vice-President—E. Martinez Rivera, M.D.

Secretary—G. Arbona, M.D.

Treasurer—Celia Guzman

Representative to the Governing Council—A. Fernos Isem, M.D.

Board of Directors: E. Quintero, M.D., Joseph Dean, M.D., Mary P. de Rahn, Isolina Rivera, R. Fernandez Marchante, M.D.

NEW GRANTS BY THE NUTRITION FOUNDATION, INC.

George A. Sloan, President of the Nutrition Foundation, New York, announced on March 13 that grants totaling \$148,550 for nutrition research during the coming year had been made by the Nutrition Foundation in accordance with recommendations of the Scientific Advisory Committee. Twenty-eight projects supported by the Foundation during 1942 were renewed, with grants totaling \$110,700, and fifteen new research projects for a total grant of \$37,850 were made. The total in research grants to forty universities since the first grants made one year ago is now \$316,000.

Charles Glen King, Ph.D., Scientific Director of the Foundation, described work that is being done under the auspices of the Foundation on amino acids, on the supply of suitable fats to the armed forces in all sections of the world, on nutrition problems relating to aviation and desert warfare, and on the effect of extremes of environment upon nutritional requirements. Dr. King stated that there is close coöperation with the officials in the Quartermaster Corps, the Surgeon General's Office, and the Department of Agriculture.

Institutions which received new grants included the University of Wisconsin, Harvard University, University of Toronto, Columbia University, University of California, Johns Hopkins University, New York University, Massachusetts State College, the University of Chicago, Yale University, Cornell University, Oregon State College and Oklahoma Experiment Station.

V. P. Sydenstricker, M.D., of the University of Georgia Medical School, was appointed a member of the Scientific Advisory Committee of the Foundation. O. C. Carmichael, Chancellor of Vanderbilt University, Nashville, Tenn., and F. G. Boudreau, M.D., of the Milbank Memorial Fund, New York, and Chairman of the Food and Nutrition Board of the National Research Council, were elected public members of the Foundation.

NEW YORK STATE ADOPTS REGULATIONS FOR HUMAN BLOOD BANKS

The Public Health Council of New York State in February adopted a new chapter of the State Sanitary Code, Chapter IV-A, which is believed to be the first regulatory action taken by a state body in the field covering human blood donors, human whole blood, human plasma, human serum or other human blood derivatives used for transfusion purposes.

The requirements prescribed are designed to meet the need for basic standards to insure the safety of human blood products. Possible dangers from the use of improperly prepared or stored human blood products for transfusion purposes were first discussed by the Council in 1941. As processing practices became more stable and it appeared that the establishment of blood plasma banks would become widespread and might include many small institutions lacking adequate equipment and qualified personnel, regulatory action was deemed desirable. The amendment has been designed to care not only for changes affecting the technical aspects of preparation of blood, but also certain over-all factors as a determination to distinguish between the requirements for commercial laboratories and other laboratories or hospitals and to regulate by requiring careful recording of basic information instead of listing certain specific requirements as to how the blood should be collected, processed, stored, and used. The purpose of the latter decision is to promote progress in the development of blood processing while fixing responsibility for the procedure on the part of the laboratory or institution.

INSTITUTE ON PUBLIC HEALTH ECONOMICS, UNIVERSITY OF MICHIGAN

A two weeks' Institute for training in the organization and management of prepayment plans of various types will open May 10, 1943, at the School of Public Health, Ann Arbor, Mich. The school is able to offer this course through a grant from the Rockefeller Foundation, made through the Committee on Research in Medical Economics, and with the aid of an Advisory Committee representing hospital, medical, coöperative, rural, and other types of health service plans. Students may

live on the campus at moderate rates. The university charges a registration fee of \$5.

The Institute is designed to meet the needs of two groups of students: (1) those already working with a prepayment plan or having a specialized interest in this field of administration; (2) those who are concerned with public health, hospital administration, or other community services and who feel it wise to learn about the growing field of health service plans. In the program of instruction, much stress will be laid on discussion. The subjects covered will include (a) the basic facts of the economic and social aspects of health services as they involve population, professions, and institutions; (b) plans of organized care of various types, their development, problems, and current issues; (c) special topics relating to the organization and administration of health service plans, *e.g.*, an intensive series on methods of appraising community medical facilities and needs, especially designed for public health people, and several technical series on management problems, statistics, and accounting connected with prepayment plans.

The instructing staff will include several members of the university faculty, all the members of the Advisory Committee, and a number of other persons concerned with the organization and management of prepayment plans and with related problems of industry, labor, governmental, and professional bodies.

The Advisory Committee includes:

Michael M. Davis, Ph.D., Chairman, Committee on Research in Medical Economics, New York

Dean A. Clark, M.D., U. S. Public Health Service, Washington

Franz Goldmann, M.D., School of Public Health, Yale University, New Haven

A. E. Larsen, M.D., California Physicians' Service, San Francisco

John R. Mannix, Michigan Hospital Service, Detroit

James C. McCann, M.D., Massachusetts Medical Service, Boston

Fred R. Mott, M.D., Farm Security Administration, Washington

Kingsley Roberts, M.D., Medical Administration Service, New York

C. Rufus Rorem, Ph.D., C.P.A., Hospital Service Plan Commission, Chicago

Henry E. Sigerist, M.D., Johns Hopkins Institute for the History of Medicine, Baltimore

E. A. Van Steenwyk, Associated Hospital Service, Philadelphia

Individuals interested in this course, and agencies which might send staff members, can obtain full information about requirements for admission, the curriculum, expenses, etc., by communicating with: Professor Nathan Sinai, Dr.P.H., The School of Public Health, University of Michigan, Ann Arbor, Mich.

NEW CHAIRMAN O.D.H.W.S. COMMITTEE ON NURSING

James A. Crabtree, M.D., the Executive Secretary, Health and Medical Committee, Office of Defense Health and Welfare Services, has announced the appointment of Marion W. Sheahan, R.N., of Albany, N. Y., Director of the Division of Public Health Nursing, New York State Department of Health, as Chairman of the Subcommittee on Nursing of the Health and Medical Committee. This subcommittee was organized in November, 1940, by the Health and Medical Committee, which in turn was set up by executive order of the President in September, 1940. Its purpose is to make over-all studies of nursing needs and to recommend methods of meeting them, as well as to coordinate all stages of the nation's wartime nursing problems. Miss Sheahan is first Vice-President of the N.O.P.H.N. and a member of the Board of Directors of the National Nursing Council for War Services. She succeeds Marion G. Howell, R.N., of Cleveland.

REPORT ON BUTTER SUBSTITUTES BY THE NEW YORK ACADEMY OF MEDICINE

The exigencies of war have created shortages in the availability of certain staple foods, butter among others. The Committee on Public Health Relations of the New York Academy of Medicine has been requested to report on oleomargarine—the present status of its production and of its adequacy as a partial replacement for butter during the present crisis.

The use of oleomargarine in this country goes back for well over half a century. Congress enacted legislation bearing on the subject as far back as 1886, two decades prior to the first Food and Drug Act. The original oleomargarine act was of a purely economic and fiscal nature. Under this act each package must be properly labeled with the word "oleomargarine" in letters three-quarters of an inch high, and the Bureau of Internal Revenue is authorized to levy an excise tax on every merchant selling the product. Every state (particularly the dairy states) has added restrictive provisions of one kind or another, such as taxes ranging from 5 to 15 cents a pound and license fees for manufacturers and venders, and in some instances licenses are necessary for restaurants, hotels and boarding houses serving margarine to their patrons. In half of the states, and this includes New York, oleomargarine cannot be served in institutions receiving tax support or subsidies. Retail license fees, state and federal taxes, state restrictions on the types of fats that may be used, and numerous interstate trade barriers have restricted its sale so that margarine is not sold in two-thirds of the retail food stores of the nation and is not available at all in some states. In many states the sale of yellow margarine is prohibited because of its resemblance to butter. The U. S. Census of Manufacturers of 1939 reports a considerable decline in the output of margarine.

This decline applied to all types of margarine whether made solely of vegetable oils or of mixtures of animal and vegetable oils and fats. As of January 1, 1943, however, by order of the War Production Board, margarine manufacturers who previously were allowed to use only 110 per cent of their average consumption of fats and oils in 1940 and 1941, were permitted to raise that figure to 180 per cent.

There has been a great deal of misinformation concerning the product. The motivation has been on purely economic grounds. We have looked into the matter solely from a nutritional and social viewpoint without regard to the economic aspects of the situation.

Definition and Standard of Identity

In June, 1941, the Federal Security Administrator, after a hearing in the matter, promulgated regulations fixing and establishing a definition and standard of identity for oleomargarine which in substance is as follows: Oleomargarine is a food, plastic in form, which consists of one or more of the various specified rendered fats, or of vegetable fats, or of a combination of animal and vegetable fats, mixed with milk or cream. In the preparation of oleomargarine one or more of the following optional ingredients may also be used:

1. Artificial coloring.
2. Sodium benzoate, or benzoic acid, or a combination of these, in a quantity not to exceed 0.1 per cent of the weight of the finished product.
3. Vitamin A, added as fish liver oil or as a concentrate of vitamin A from fish liver oil (with any accompanying vitamin D and with or without added vitamin D concentrate), in such quantity that the finished oleomargarine contains not less than 9,000 United States Pharmacopoeia Units of vitamin A per pound.
4. The artificial flavoring diacetyl added as such, or as starter distillate, or

produced during the preparation of the product as a result of the addition of citric acid or harmless citrates.

5. (a) Lecithin, in an amount not exceeding 0.5 per cent of the weight of the finished oleomargarine; or (b) monoglycerides or diglycerides of fat-forming fatty acids, or a combination of these, in an amount not exceeding 0.5 per cent of the weight of the finished oleomargarine; or (c) such monoglycerides and diglycerides in combination with the sodium sulfo-acetate derivatives thereof in a total amount not exceeding 0.5 per cent of the weight of the finished oleomargarine; or (d) a combination of (a) and (b) in which the amount of neither exceeds that above stated; or (e) a combination of (a) and (c) in a total amount not exceeding 0.5 per cent of the weight of the finished oleomargarine. (The weight of diglycerides in each of ingredients (b), (c), (d), and (e) is calculated at one-half actual weight.)

6. Butter.

7. Salt.

Most manufacturers use vegetable fats, particularly coconut, peanut, and cottonseed oils, in preference to animal fats or oils because these ingredients have less tendency toward rancidity, and they have taken advantage of the regulation permitting the addition to the product of 9,000 units of vitamin A per pound.

From a nutritional viewpoint, when it is fortified with vitamin A in the required amount, oleomargarine is the equal of butter, containing the same amounts of protein, fat, carbohydrates, and calories per unit of weight. Moreover, since the minimum vitamin A content of "enriched" oleomargarine is fixed and the amount of this vitamin in butter may range from 500 to 20,000 units per pound, "enriched" oleomargarine is a more dependable source of vitamin A than is butter. Since it is a cheaper product than butter, fortified oleomargarine constitutes a good vehicle

for the distribution of vitamin A and fats to low-income groups and should therefore be made available to them.

Under the standards set by the Food and Drug Administration, oleomargarine is as clean and sanitary a food as butter. The two products are likewise equal in digestibility. Their relative palatability is a matter of individual taste.

Conclusions and Recommendations

In order that the health of the population may not be impaired by the adoption of a diet insufficient in fats and fat soluble vitamins, the committee recommends that the manufacture, distribution, and consumption of oleomargarine be encouraged and suggests specifically:

1. That the regulations set by the Federal Security Administrator in 1941 be amended to make it mandatory that all oleomargarines be fortified with vitamin A at a uniform level of 9,000 United States Pharmacopoeia Units per pound of finished product;

2. That the War Production Board be requested to allow the use of fats and oils for the manufacture of oleomargarine in such quantities as would offset the necessary withdrawal of butter from civilian use;

3. That federal and state laws which restrict the manufacture and distribution of oleomargarine be suspended for the duration of the butter crisis;

4. That wide publicity, both lay and professional, be given the fact that oleomargarine, fortified by vitamin A, is nutritionally equal to butter; and

5. That this matter be brought to the attention of the President of the United States, the Secretary of Agriculture of the United States and his Technical Assistant on Civilian Requirements, and the Commissioner of Agriculture and Markets of New York State.

CINCHONA FELLOWSHIPS

The Cinchona Products Institute of New York has announced that two

Fellowships are offered for clinical or pharmacological research on quinine or the other alkaloids of cinchona. The Fellowships carry a yearly stipend of \$2,000, plus necessary laboratory or routine expenses. Further details may be secured from the Institute, 10 Rockefeller Plaza, New York, N. Y.

GALLUP POLL TESTS WARTIME EATING HABITS

In order to discover how much the average American adult knows about simple nutrition rules and where an educational program may be needed, the American Institute of Public Opinion recently conducted a nation-wide survey in which a record of the principal foods consumed by representative adults in all states was obtained for a 24 hour period. Results were compared with a list of essential foods recommended by the Bureau of Home Economics of the Agriculture Department and other nutrition experts.

The comparison is shown below. The figures represent the number of persons who ate none at all of the foods listed as necessary daily in each category:

<i>Food Recommendations</i>	<i>How Adult Americans Live Up to Them</i>
Fruits and Raw Greens: tomatoes, citrus fruits or juices, raw cabbage, or salad greens	45% had none
Eggs: 1 a day	48% had none
Milk and/or Cheese	34% had none
Vegetables: leafy green or yellow	25% had none
Meats: meat, fish, or poultry	12% had none
Other Vegetables (including potatoes) or Fruit	8% had none
Cereals or Bread: whole grain or enriched	3% had none

"The greatest deficiencies in the national diet are apparently the citrus fruits and raw greens, eggs, and dairy products. Although health authorities recommend one pint of milk a day for adults (one quart for children), more than one-third of all adults in the survey

consumed no milk or ate no cheese. Taking milk alone, the survey found that 43 per cent had consumed none, while 57 per cent included at least some milk in their diet.

"While the Bureau of Home Economics recommends that the foods listed in the table above be eaten every day, it does allow some latitude in consumption of eggs, considering three or four a week sufficient. Although 48 per cent in the survey said they had no eggs, some may have overlooked eggs used in cooking.

"The campaign of health authorities to induce people to eat more leafy green and yellow vegetables is apparently making progress. Three-fourths of all persons in the survey lived up to the rule. The proportion is likewise high for consumption of potatoes, other vegetables (beets, cauliflower, corn, cucumbers, onions, turnips, etc.), and other fruits (apples, bananas, berries, melons, prunes, etc.). That Americans are a nation of meat eaters is likewise shown by the fact that only 12 per cent had no meat, fish or poultry.

"Sharp differences in dietary habits were found by income groups. In the lower group the outstanding deficiencies, as compared to other income groups, were citrus fruits and raw greens; eggs; milk; and leafy green or yellow vegetables.

PERCENTAGE LACKING FOOD REQUIREMENTS

	<i>Upper Income</i>	<i>Middle Income</i>	<i>Lower Income</i>
Citrus Fruits & Greens	24%	35%	56%
Eggs	45	43	52
Milk, Cheese	27	26	40
Vegetables (leafy and yellow)	19	21	29
Meats, Fish, Poultry	7	8	15
Other Vegetables	6	6	10
Cereals or Bread	3	2	3

"Among geographical sections, the South shows a greater deficiency than any other section in citrus fruits and raw greens, while the New England and

Middle Atlantic area shows greatest deficiency in milk or milk products."

NATIONAL DIET PICTURE BY SECTIONS
Percentage Lacking Food Requirements

	N. Eng. and M. Atl.	East Cent.	West Cent.	South West	Far West

REPORT ON SCHOOL HEALTH

A report of the Committee on School Health of the American Academy of Pediatrics, published in the February 20 issue of the *Journal of the American Medical Association*, will have special interest for members of the Maternal and Child Health, the School Health and the Health Education Sections. It proposes a plan of administration through which the professions of education and medicine might work together to educate parents and children to use curative and preventive medicine intelligently. The report includes proposed professional qualifications for medical personnel in the schools. Reprints may be secured from Dr. Clifford G. Grulee, American Academy of Pediatrics, 636 Church Street, Evanston, Ill.

NEWS OF THE O.C.D. MEDICAL DIVISION

Dr. George Baehr, Chief Medical Officer of the Office of Civilian Defense, Washington, has spent two weeks recently in Hawaii at the invitation of the Governor of the Territory and in conference with local authorities on civilian defense activities, which are being reor-

ganized now that the government of the Island is in the process of being transferred from the Army to civil authority.

Dr. Hamilton Southworth of the staff of the Medical Division, O.C.D., has gone to London, England, as a medical liaison officer with the British Office of Home Security.

James M. Landis, the U. S. Director of Civilian Defense, has announced that arrangements have been made for the Civil Air Patrol to fly blood plasma supplies into stricken areas in the event of emergencies.

Dr. Dudley A. Reekie, Boston, Regional Medical Director of the First Civilian Defense Region, has been serving as Chief of the Field Casualty Section of the Medical Division in the absence of Dr. Leonard A. Scheele, who is assigned to special duty.

HEBREW UNIVERSITY WANTS JOURNALS

The Hebrew University Library of Jerusalem is seeking to obtain back numbers of the AMERICAN JOURNAL OF PUBLIC HEALTH in order to complete its files. Will any person having such back numbers or complete volumes who wishes to donate them to the Hebrew University, please communicate with Jerome Trichter, Bureau of Food and Drugs, 125 Worth Street, New York, N. Y. The following are the numbers desired.

Volume 1 to 8	(1911-1918)—All numbers
9	(1919)—No. 2 to No. 12
10	(1920)—All numbers
18	(1928)—No. 8
20	(1930)—No. 1
22	(1932)—No. 3 and No. 4
23	(1933)—No. 2, No. 4, No. 6 to No. 12
24	(1934)—No. 9
25	(1935)—No. 6, No. 9, No. 11 and No. 12

All arrangements for shipping the donated material and costs will be taken care of by Mr. Trichter.

PERSONALS

Central States

FRED P. BESTGEN, M.D.,† formerly of Rapid City, S. D., has been appointed Director of the Hall-Adams Health Unit, Nebraska.

G. C. BROWN, M.D., of Newton, Ill., has joined the Peoria City Department of Health as Clinic Physician for the Well Baby Clinic, Maternity Centre, and the school clinics.

CONRAD A. ELVEHJEM, Ph.D.,† Professor of Biochemistry, University of Wisconsin, Madison, has been awarded the Willard Gibbs Medal by the Chicago Section of the American Chemical Society. It will be presented formally to Dr. Elvehjem May 20.

CORNELIUS A. HARPER, M.D.,* of Madison, retired on January 28 as State Health Officer, a position he has held since April 1, 1904. He has been a member of the Board since February, 1901. CARL N. NEUPERT, M.D., of Madison, who has been Assistant State Health Officer for 6 years, has been named Secretary to the Board of Health and State Health Officer. Dr. Harper has been named Medical Specialist in Public Health to the State Board.

VIRGINIA B. HICKERSON, M.D., has been appointed Pediatrics Coördinator for the Anti-Tuberculosis League of Cincinnati and Hamilton County, Ohio, succeeding BARBARA A. HEWELL, M.D.

EDWIN HALL JORRIS, M.D.,† of Madison, Supervisor of Local Health Services and Director of the Division of Tuberculosis Control of the Wisconsin State Board of Health, has been commissioned a lieutenant commander in the medical corps of the U. S. Naval Reserve.

PROFESSOR MAX LEVINE,* of the Department of Bacteriology, Iowa State

College of Agriculture and Mechanic Arts, at Ames, is serving with the Sanitary Corps, having recently been promoted to the rank of Lieutenant Colonel. At present he is in the Brooke General Hospital, Fort Sam Houston, Texas. Three of Dr. Levine's sons are serving in the Army: Lt. Norman D. Levine, Sanitary Corps; Lt. S. Edgar Levine, Engineer Corps; and Lt. Melvin L. Levine, Field Artillery.

STEPHEN V. LUDDY, D.D.S., M.P.H.,† Director of Oral Hygiene in the North Dakota State Department of Health, Bismarck, N. D., resigned January 1, 1943, to accept a position as Director of the Bureau of Dental Health of the West Virginia State Health Department, Charleston, W. Va.

KARL M. MASON has resigned from the staff of the Department of Health of Ingham County, Mich., to accept the position of Public Health Engineer with the Division of Sanitation, of the Peoria, Ill., Department of Health, effective February 15.

HAZELETT A. MOORE, M.D., of Oxford, Ohio, Chairman of the Butler County Board of Health since 1939, has been appointed Health Commissioner of Butler County, succeeding CLIFFORD J. BALDRIDGE, M.D.,† resigned.

JOSEPH B. STOCKTON, M.D., of Cleveland, Ohio, Medical Director of the Cuyahoga County Tuberculosis Dispensary, has been appointed Controller of Tuberculosis for Cuyahoga County.

BUELL H. VAN LEUVEN, M.D.,† of Traverse City, Mich., has been appointed in charge of the new district health unit recently formed when

* Fellow A.P.H.A.

† Member A.P.H.A.

Leelanau County joined with the Grand Traverse County Department of Health, which has functioned since April, 1939.

JAMES F. WILSON, M.D.,† of Washington Court House, Ohio, until recently Health Commissioner of Fayette County and Secretary for many years of the Fayette County Medical Society, has been appointed Health Commissioner of District No. 4 of the Michigan Department of Health, with headquarters in Rogers City, Mich.

ANDREW C. WOOFER, M.D., of Hot Springs, Ia., has been assigned to Iowa by the U. S. Public Health Service to direct the state's venereal disease program during the war period. He succeeds REGNAR M. SORENSON, M.D., C.P.H.,* who is now on active duty with the Reserve Corps of the U. S. Public Health Service at the Iowa State Board of Health, Topeka.

Eastern States

GERTRUDE E. HODGMAN, R.N., who for 2 years has been Director of the Russell Sage College School of Nursing, Troy, N. Y., has been appointed by the Coördinator of Inter-American Affairs as Director of Nurses' Training in the Ministry of Health and Education of Brazil. She will assume the new post in June. Miss Hodgman will be succeeded at Troy by KATHARINE G. AMBERSON, who has been Director of Clinical Nursing Education.

ELLEN C. POTTER, M.D.,* of Trenton, N. J., has been appointed as Director of Medicine and Chairman of the Child Care Committee of the Office of Civilian Defense Director of the State of New Jersey.

MRS. MAX J. H. ROSSBACH is the new Director of Child Care for the American Women's Voluntary Services in New York, N. Y.

Southern States

GEORGE M. COOPER, M.D.,† of Raleigh, has been named President of the North Carolina Academy of Public Health recently organized by the North Carolina State Laboratory of Hygiene, Raleigh, N. C. Dr. Cooper is Assistant State Health Officer and Director of the Division of Health Education, Crippled Children's Work, and Maternal and Child Health Service.

MARIE ELIZABETH F. GENTRY, M.D.,† was recently named Director of the Maternal and Child Health Division of the Austin [Texas] City Health Department, succeeding WILLIAM W. KELTON, JR., M.D.,† who has entered the Army Air Corps.

J. LEE HARWELL, M.D., of Poplar Bluff, Mo., was appointed to the City Board of Health on December 30.

RAYMOND HUSSEY, M.D., Associate Professor of Medicine, Johns Hopkins University School of Medicine, Baltimore, Md., and a member of the Council on Industrial Health, American Medical Association, Chicago, Ill., has been appointed Scientific Director of the new Army Industrial Hygiene Laboratory at Johns Hopkins University School of Hygiene and Public Health. The Laboratory will operate under the direction of the Occupational Hygiene Branch of the Preventive Medicine Division of the Office of the Surgeon General of the Army.

ROY A. KELLY, M.D., of New Roads, La., Director of the St. Charles Parish Health Unit, was recently assigned in charge of the Jefferson Davis Health Unit.

WILLIAM C. D. McCUSKEY, M.D.,† of Wheeling, W. Va., has been appointed a member of the Public Health Council for the term ending June 30,

* Fellow A.P.H.A.

† Member A.P.H.A.

1945, succeeding ALBERT H. HOGE, M.D., of Bluefield, Md.

ABRAHAM OPPENHEIM, M.D.,† of Arcadia, La., Director of the Bienville Parish Health Unit, has been appointed in charge of the units in Vermillion and New Iberia Parishes.

RUTH G. TAYLOR, M.A., R.N.,† of Washington, D. C., has been appointed Director of the Nursing Unit of the Division of Health Services, U. S. Children's Bureau, Department of Labor, Washington, succeeding NAOMI DEUTSCH, R.N.,* resigned. Miss Taylor has recently been a member of the staff of the International Health Division, Rockefeller Foundation, and has been stationed in Europe. Previously she was Public Health Nursing Consultant of the Children's Bureau, stationed in San Francisco.

Western States

JOHN HALL * has left the Clark County Department of Health, Las Vegas, Nev., to join the Territorial Health Department, Juneau, Alaska.

ANDREW M. HARVEY, M.D., has been appointed Assistant City Health Officer of Long Beach, Calif. He succeeds FREDERICK G. HALL, M.D., who had been Acting Assistant Health Officer under FRANK W. STEWART, M.D.,† but who has retired.

F. RUTH KAHL, R.N.,* who has been Public Health Nursing Consultant in U. S. Public Health Service District No. 8, with headquarters in Denver, has been assigned as Nursing Consultant with the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md., beginning in January.

JOHN A. KAHL, M.D., M.P.H.,† District Health Officer with headquarters at Walla Walla, Wash., has resigned to become Assistant Director of Health of Washington. The

district of which he has been head includes Walla Walla, Benton, and Franklin Counties. At one time Dr. Kahl had served as Director of Local Health for the State Department of Health and as Health Officer of Clark County.

FREDERICK M. PETRIE, M.D., has been appointed Health Officer of Toppenish, Wash., succeeding ANGUS MEAGHER, M.D., who has gone into military service.

DEATH

DR. JOSEPH F. X. STACK, Health Commissioner of Hoboken, N. J., since 1911, died February 17, at the age of 72.

* Fellow A.P.H.A.

† Member A.P.H.A.

Comparative Speed of Response of Previously Immunized and Non- Immunized Children to Fluid and Alum- Precipitated Diphtheria Toxoid*

VLADIMIR K. VOLK, M.D., D.P.H., F.A.P.H.A., WILLIAM
EDWARD BUNNEY, Ph.D., F.A.P.H.A., AND
JOHN T. TRIPP, Ph.D., F.A.P.H.A.

*Commissioner of Health, Saginaw, Mich.; Director, E. R. Squibb & Sons,
New Brunswick, N. J.; and State Department of Health, Lansing, Mich.*

IN an earlier paper¹ preliminary observations were reported suggesting that those previously immunized would respond quickly to a single injection of either fluid or alum-precipitated diphtheria toxoid. It was felt that this observation might be of value to the health officer faced with an epidemic of diphtheria in a partially immunized community. He might be well advised to give a single injection of fluid or alum-precipitated toxoid to all those with a history of previous diphtheria immunization. This study was designed to give more conclusive evidence on the quickness of the response of previously immunized children and to determine whether there was any difference in the quickness of the response following fluid

as compared with alum-precipitated toxoid.

METHODS

The antitoxin content of the blood of the children was determined just before giving the reimmunization injection and at 5 and 10 days after the injections. A control group of children with no history of previous immunizations were also studied. The reimmunizing injections were 0.5 ml. of fluid or alum-precipitated toxoid, because an earlier study² had shown that either of these procedures was safe and effective in routine reimmunization. The toxoids, the method of bleeding, and the method of antitoxin titration, were the same as used in a previous study.²

RESULTS

The total number of children with a history of previous immunization in-

cluded in the study was 112. The date of their previous immunization experience is given in Table 1.

The age distribution of the children at the time of their primary immunization and of their reimmunization is given in Table 2.

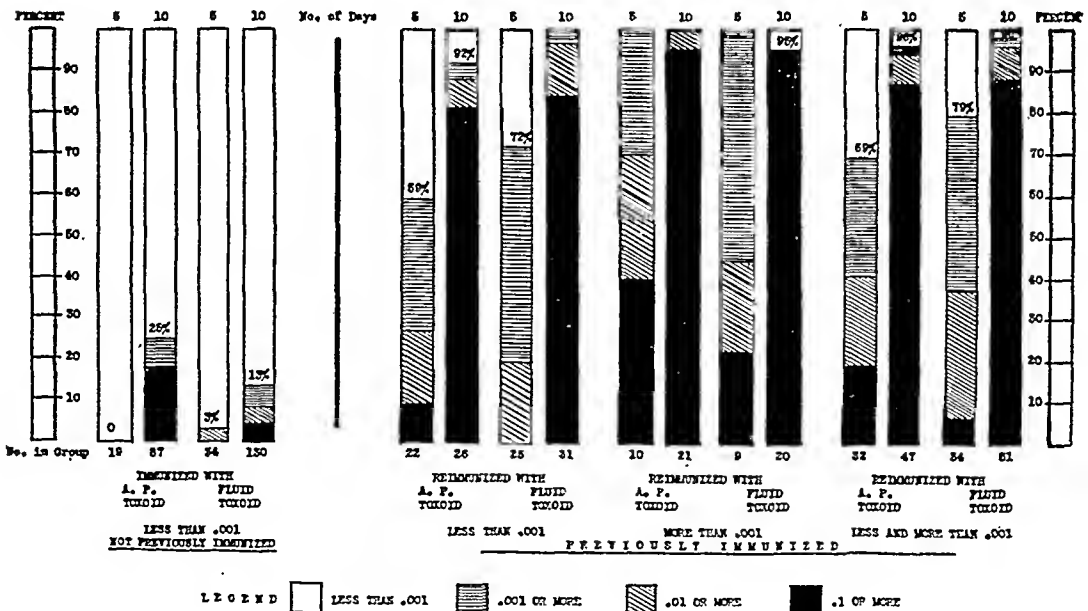

It can be seen that most of the children were 6-9 years of age at the time of primary immunization and were reimmunized approximately 4 years later.

The results of the reimmunization are summarized, and compared with the response to primary immunization, in Table 3.

It can be seen that of 98 children who had previously received a complete immunizing treatment with fluid or alum-precipitated toxoid, and of whom 57 or approximately half had less than 0.001 unit of antitoxin at the time of reimmunization, the injection of 0.5 ml. of fluid or alum-precipitated toxoid re-

sulted in 97 per cent of the children developing 0.001 unit or more within 10 days. Moreover 96 per cent of the 57 children with less than 0.001 unit at the time of reimmunization developed 0.001 unit or more in 10 days. This quick response in a high percentage of previously immunized children is in marked contrast to the response of 87 children with no history of previous immunization and less than 0.001 unit. Only 25 per cent of these developed 0.001 unit within 10 days of similar 0.5 ml. injections of fluid or alum-precipitated toxoid.

There is also a suggestion in Table 3 that fluid toxoid is just as effective as alum-precipitated toxoid in bringing about a quick response in those previously immunized. This is in sharp contrast with the greater effectiveness of alum-precipitated toxoid in primary immunization.

SAGINAW COUNTY DEPT. HEALTH 1946

CHART 1—Comparison of antitoxin response at the end of five and ten days to a single injection of fluid or alum-precipitated toxoid in a group not previously immunized and in a group which previously received a satisfactory immunization (Two or more doses of fluid or one or more doses of A. P. Toxoid)

The results in Table 3 showing the response after reimmunization of those who had received satisfactory primary immunization are presented diagrammatically in Chart 1. The difference in the rapidity of response between those with and those without primary immunization and having less than 0.001 unit at the time of injection is readily apparent.

At least 59 per cent of those previously immunized have increased from less than 0.001 unit to 0.001 unit or

more within 5 days as contrasted with not over 3 per cent in those tested after primary immunization.

The influence of the nature of the primary immunization on the reimmunization response is evaluated in Table 4.

Although the numbers studied are small it would appear that if at least one injection of alum-precipitated toxoid or 2 injections of fluid toxoid are given in primary immunization a quick response will result in reimmunization of

children with less than 0.001 unit at the time.

One important question is, "How long after primary immunization will children respond quickly to a single 0.5 ml. injection of fluid or alum-precipitated toxoid?" The results are analyzed with this in mind in Table 5.

Here again the figures in each group are small but there is no indication of a falling off in responsiveness after 5 years even in those children with less than 0.001 unit of antitoxin at the time of reimmunization.

DISCUSSION

It would seem reasonable in the light of these results to advise giving a single

0.5 ml. injection to all previously immunized children when faced with a possible diphtheria epidemic in a community either partially or fairly completely immunized. One would expect this procedure to result in the developing within 10 days of adequate immunity in at least 95 per cent of those whose primary stimulation was given less than 6 years before. Responsiveness to reimmunization may very well last longer than 6 years, but this study reports no data on this point.

This procedure may result in the saving of time and money in the control of an epidemic such as that reported by Turner³ where the giving of prophylactic antitoxin to all contacts had to

be resorted to, and where diphtheria persisted over a 26 day period and cases developed in previously immunized children.

The children receiving the reimmunizing injection will have an increase in their antitoxin titer which will protect them for a long time—a decided advantage over the use of prophylactic antitoxin which protects for only a few days and moreover may sensitize the child so as to make subsequent injections of any antitoxin of horse origin difficult if not dangerous.

SUMMARY

At least 97 per cent of a group of 98 previously immunized children receiving a reimmunizing injection of 0.5 ml. of fluid or alum-precipitated diphtheria toxoid developed 0.001 unit or more diphtheria per ml. of serum within 10 days. At least 74 per cent developed 0.001 unit or more within 5 days. Moreover, at least 94 per cent developed

0.01 unit or more and 88 per cent developed 0.1 unit or more within 10 days. Consequently this reimmunizing procedure is recommended for use in the face of a threatening diphtheria epidemic for protection of previously immunized children.

ACKNOWLEDGMENT—We gratefully acknowledge the technical assistance of Anna Sonderman, R.N., Anita Leavitt, Mary E. Gottschall, and Nina Smith, of the Diphtheria Committee Staff for their untiring efforts.

We also appreciate the coöperation of Dr. C. C. Young, Director of the Bureau of Laboratories, Michigan Department of Health, Lansing, and members of the Nursing Staff of the Saginaw County Health Department, Doris Gleason, R.N., and Henrietta Wattman, R.N., and to Ray Ilgen, all of whom have been very helpful to us in carrying out the study.

Public Health Implications in City and Regional Planning*

HARLAND BARTHOLOMEW

Engineer, City Plan Commission, St Louis, Mo.

BY city and regional planning we seek to control the design and arrangement of the city for convenience, safety, and maximum possible satisfactory living conditions. Three levels of planning are involved: the city or region, the neighborhood, and the relationships of individual structures.

There are public health implications in planning at each of these levels. There is need for open spaces to break up excessive continuity of building masses. There is need for open spaces for recreation, both active and passive. There is need for orderly arrangement to reduce fatigue caused by undue loss of time in travel between home and work, to reduce congestion and confusion in transportation, and to reduce accident hazards. There is need for good neighborhood environment with freedom from the noises, odors, and traffic of commerce and industry, and with opportunity for recreation for different age groups and for normal community life. There is need for sufficient open space between buildings to permit adequate light and air to encourage rest and normal family life.

These are city and regional planning matters because they cannot be secured and permanently preserved by the individual at any cost. They are inadequately provided for in cities today because of haphazard growth prior to the advent of city and regional plan-

ning, and because they will not be provided voluntarily by traditional speculative building processes that furnish about 90 per cent of our dwelling construction.

From the planning viewpoint, these objectives are matters more or less directly related to public health because they reduce the danger of transmission of disease and of accident, because more light, air, and recreation afford opportunity for energy building resistance to disease, because noise, crowding and congestion produce nervous strain, and because pleasant living conditions are less productive of emotional disorders.

If we could design and build a modern city today with a completely fresh start, its design and character would be radically different from the cities we now know. We are greatly handicapped in modern city and regional planning with having to deal with such vast areas of haphazard urban growth. It is infinitely more difficult to replan than to plan anew. An even greater handicap is the inability of government to anticipate changing conditions and to provide quickly the controls needed. You who are engaged in public health activities are well aware of this situation.

Since planning activity is directed both to the correction of mistakes in past development and to the control of new development, the character and effectiveness of planning in each of these categories are markedly different in degree.

* Presented before the Engineering Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

Planning is but one of several forms of administrative activity directed to raising the standards of public health. Hence, in that which follows, there is no attempt to appraise the specific health value of planning actions. There are described certain activities which those engaged in planning believe have certain relation to or implications in public health. If you who are best qualified to judge agree that these implications are tenable, this paper will not have been prepared in vain.

The legal recognition of health implications in city planning is found in the Standard City Planning Enabling Act published by the U. S. Department of Commerce in 1928, and which has now been adopted and is in effect in approximately one-half of the states of the Union. In this act it is provided:

"*Sec. 7. Purposes in View.* In the preparation of such (city) plan the commission shall make careful and comprehensive surveys and studies of present conditions and future growth of the municipality and with due regard to its relation to neighboring territory. The plan shall be made with the general purpose of guiding and accomplishing a coordinated, adjusted, and harmonious development of the municipality and its environs which will, in accordance with present and future needs, best promote health, safety, morals, order, convenience, prosperity, and general welfare, as well as efficiency and economy in the process of development; including, among other things, adequate provision for traffic, the promotion of safety from fire and other dangers, adequate provision for light and air, the promotion of the healthful and convenient distribution of population, the promotion of good civic design and arrangement, wise and efficient expenditure of public funds, and the adequate provision of public utilities and other public requirements."

In the Standard State Zoning Enabling Act published by the U. S. Department of Commerce in 1926, which act has been adopted in all states, the following language occurs:

"*Sec. 1. Grant of Power.* For the purpose of promoting health, safety, morals, or the general welfare of the community, the legisla-

tive body of cities and incorporated villages is hereby empowered to regulate and restrict the height, number of stories, and size of buildings and other structures, the percentage of lot that may be occupied, the size of yards, courts, and other open spaces, the density of population, and the location and use of buildings, structures, and land for trade, industry, residence, or other purposes."

The daily activities of city planners are directed to the attainment of these objectives, among which it is to be noted that health is a primary consideration. In the preparation and administration of comprehensive city plans, the following prerequisites of public health are kept so constantly in mind that their application becomes virtually automatic:

1. A more orderly development of the city
2. Adequate supply of light
3. Adequate supply of pure air
4. Reduction of congestion
5. Reduction of traffic hazards
6. Reduction of noise, odors, and other nuisances
7. Prevention of slums
8. Improvement of recreational facilities
9. Improvement of residential environment

As stated above, these matters are not the exclusive concern of the city planner. Public health officials and certain administrative officers and agencies are equally concerned. Building codes, sanitary codes, minimum standard housing ordinances, laws regulating the control of nuisances, and such, all are directed toward these same ends. The highest standards of public health will be reached where all of these efforts are coordinated most effectively.

Ways and means employed by city planners in carrying out the objectives enumerated are described below:

1. *A more orderly development of the city—*

Zoning is one of the most important planning tools. By confining single-family dwellings, flats, multiple dwellings, stores and industries to separate districts, and by prescribing maximum

building heights and minimum open space standards for each according to type, we can restore order in the city. This has been accomplished in newer suburban developments which had the advantage of zoning from their inception. This accounts for much of the shift of population from more centrally located older districts. Good order cannot be restored in these older districts, however, without large scale reconstruction.

We have not made most effective use of zoning in cities as yet. Larger districts or zones should be delineated, and greater autonomy in each is needed. Better standards of open space for multiple dwelling areas especially should be adopted and enforced. Speculative pressures for spot zoning by lots or blocks can soon destroy the fundamental values of separation of building types, and may soon lead to the same degree of confusion and conflict produced by haphazard, uncontrolled development.

Much has been said and written about the decentralization trends that have characterized recent city growth. Decentralization, *per se*, will not solve many urban problems. It may create greater problems of transportation and enormous waste in time losses and in the cost of delivery of goods. In city planning we often speak of balanced development of cities by which is meant an orderly design and arrangement which will minimize the wastes of excessive congestion, on the one hand, and of excessive scattering on the other. We have learned much about the wastes of congestion, but we are just beginning to discover some of the wastes incurred by excessive spread of the area of urbanization.

More healthful cities and more efficient and economical cities can be designed if we have the vision and the courage to make bolder comprehensive plans.

2. Adequate supply of light—

Building codes contain regulations for certain window areas in relation to room size where people live and work, with the object of permitting adequate light, air, and sunshine to gain admission to these rooms. Where buildings are close together, or where they are overshadowed by buildings of greater height, the extent of direct admission of sunlight is limited. Building codes control the design of individual buildings, but not the relationships of light and air around buildings or between buildings. In city planning, and especially in zoning regulations, standards are established for certain minimum distances between buildings, which are varied according to the type of district and the height or the length of the building. Prior to zoning, lots in most cities were too narrow, and side yards, if provided, were not required to be in excess of 2 or 3 ft. Such standards of open space are as outmoded as the horse and buggy. Gradually we are increasing the width of side yards through zoning ordinances and in land subdivision regulations to a minimum of 6 or 8 ft. for single-family dwellings, and to 10 ft. or more for multiple dwellings. A minimum distance of 50 ft. between buildings in block interiors is assured in new developments by zoning regulations which require a minimum depth of rear yard of 25 ft. for each building.

When zoning regulations were first undertaken, it was believed that more and more high buildings in cities were inevitable. Subsequent experience has shown that numerous high buildings are neither necessary nor desirable. There is ample land for building in cities without overbuilding in certain sections. In most zoning ordinances building height regulations have been lowered in order to provide for a more uniform development. In the various zones building heights have been adopted which are in harmony with the prevailing type of

building development, $2\frac{1}{2}$ stories for one- and two-family dwellings, 3 stories for most multiple dwellings, from 3 to 12 stories for commercial development, according to location, 8 stories for industry.

By increasing the size of yards and adopting reasonable height regulations, a more ample supply of light and sunshine is assured for individual dwelling structures.

In business districts, the newer types of zoning regulations for building height control limit the height of walls at the street line and invite a pyramidal type of structure, thus affording more satisfactory offices assured of more direct admission of sunlight. Examples of such structures may be seen here in St. Louis. These have building walls at the street line only 2 or 3 stories high, even though the structure rises to several hundred feet in height in the middle of the block.

There is no need for dark, poorly lighted and ventilated rooms in multiple dwellings, and comparatively small need for them in most office buildings except in high value areas of the largest cities. The great progress made in artificial lighting and ventilation is acknowledged. How far this can be substituted for natural light and sunshine it is difficult to determine.

3. *Adequate supply of pure air—*

Where large numbers of people come together in cities, it is important to control those things which interfere with an adequate supply of pure air. By zoning large areas for exclusive residential use, we have reduced contamination of the air by smoke, dust, and odors from commercial and industrial structures in close proximity.

By increasing the size of lots, the minimum width of side yards, and the minimum depth of rear yards, there is greater opportunity for circulation of

air in the community, as well as around the individual structures.

In zoning ordinances and land subdivision regulations, it has become customary to require greater recession of buildings from the street line. Minimum front yard depths of 25 or 30 ft. are becoming the custom rather than the exception. In so doing, the distance between buildings on opposite sides of the street is increased and the long, continuously wide open space thus created improves the opportunity for circulation of air. Where traffic is heavy, and especially where buses and trucks operate in considerable numbers, there is much contamination of the air with fumes and dust. By keeping the dwellings well back from the street lines, occupants are less disturbed by the dust and odors created by street traffic.

By increasing the size of individual lots, yards, and building setbacks, improved opportunity is afforded for the growing of grass, trees, and shrubs. These are beneficial agents in purification of the air.

The older sections of American cities were built so compactly, and land values became so high, that few large community open spaces were provided. With the advent of the automobile, it became possible for much of the urban population to seek less congested living conditions in outlying sections of the city. Many of the older congested districts of the city are now obsolete and must be rebuilt. Where this is done, new open spaces can be provided in the form of parks and parkways, which will afford improved opportunities for air circulation. The new, large housing developments afford much improved standards of light and air for individual dwelling structures. Our studies show that we can rehouse populations in these areas at the same density levels with far less street space, little or no increase in building height, and with a reduction

in land coverage from 60 per cent to as low as 20 or 30 per cent.

Many of the new public housing projects have far less land coverage than was found in the original development. Certainly, no one can see these projects without being impressed with the greatly improved conditions so far as light, air, and sunshine are concerned. The effect upon public health is bound to be tremendously beneficial. Such benefits cannot be secured through reconstruction of individual buildings on individual lots.

4. *Reduction of congestion—*

There is ample land in most cities for building development without unnecessary crowding and congestion. Sir Raymond Unwin's well known paper, "Nothing Gained by Overcrowding," contains convincing proof of this fact. Much overcrowding of the land in cities is the result of speculative pressure rather than of popular demand. New York's Lower East Side contains 250,000 less population today than in 1910. We have lost more than 125,000 population in the area east of Jefferson Avenue in St. Louis. Where population leaves congested areas of cities in such enormous numbers, it is striking evidence of dissatisfaction with living conditions. Inquiries conducted by housing investigators of the City Plan Commission of St. Louis in these older areas disclosed that the principal reasons why occupants desired to leave were all related directly to matters of public health, such as desire for more open space, for grass, trees, shrubs and flowers, for more cleanly conditions, and for a better atmosphere in which to bring up their children.

Excessive population congestion is being controlled through zoning ordinances. In recent years we have found that it is not enough to control the use of land, the type of buildings, the height

of building, the size of yards, and the percentage of lot coverage, but that an equally effective measure of control is the direct regulation of population density through specification of the square feet of lot area per family to be housed in each new building according to the character of the district in which it is to be located. Future overcrowding of land can and will be prevented.

Another device used in many zoning ordinances to prevent overcrowding of land is the prevention of rear lot dwellings in many zoning ordinances. Each building must occupy a separate lot having direct frontage upon a public street or officially approved private street or place.

In zoning ordinances it is provided that new multiple dwelling structures shall be so designed that cellars shall not be used for dwelling purposes. Zoning regulations usually provide, also, that if basements are designed for use as dwelling quarters, the basement shall be considered a story in height measurement.

We no longer regulate building height by measurement in feet, because this led to a reduction in story heights in order to squeeze in a greater number of stories. Zoning height regulations now specify the number of stories permitted in addition to a maximum height measured in number of feet.

Since we have learned more about the undesirability of crowding the land, we are gradually reducing the number of districts and area of districts wherein high buildings are permitted.

There has been excessive overcrowding of the land with high buildings in central business districts of many cities. Two forces have operated to prevent further mistakes of this character. First, it has been found that high buildings are not good financial risks. Second, where many tall buildings are brought together in close proximity, there is excessive crowding of the streets

and transportation facilities. By city planning we have reduced this congestion by opening new and wider streets, thus enlarging the central traffic district, by building by-pass thoroughfares, and by establishing a lower maximum building height limit. These measures have had the effect of spreading new building construction, and thus relieving over-concentration within a small area.

Two important parts of the comprehensive city plan are the major street plan and the transit plan. By opening up new approach thoroughfares to central business districts, and by creating more direct, capacious crosstown thoroughfares, many street traffic congestion problems are solved which could not be solved in any other way. These improved new street plans afford opportunities not only for more expeditious movement of vehicular traffic, but have been designed with a view to providing improved opportunities for movement of mass transportation carriers like street cars and buses. Time-consuming delays and time spent by individuals on mass transportation vehicles have been greatly reduced. As previously stated, however, these time savings may be lost through increasing distances of travel if expansion of the area of urbanization is uncontrolled.

5. *Reduction of traffic hazards—*

American cities were not prepared for the advent of the automobile. For the most part, streets were narrow and were laid out in the familiar gridiron pattern, which assumed more or less uniform use. With the coming of the automobile, the hazard of street accidents was universal. By city planning we developed major street plans, comprised of systems of wide, main thoroughfares to accommodate the great bulk of automobile traffic flow, and thus to reduce the traffic and the hazard in minor residence streets. This differentiation has

been encouraged by reducing the width of pavements on minor streets, by providing less satisfactory surfacing for heavy traffic, and by occasionally blocking off minor streets, some temporarily, some permanently.

While the traffic hazard has been reduced on minor streets, there was a corresponding increase of the traffic hazard on the main thoroughfares. Here traffic control devices have been designed with a view to expediting vehicular traffic and providing safety controls for the pedestrian traffic, including the design and construction of safety islands, loading zones, pedestrian underpasses, and such. Most recent major street plans include designs for superhighways, completely grade-separated, which will still further reduce the traffic hazard for pedestrians. In the design of major streets and superhighways, there is constant attention to plans for reducing traffic hazard to the pedestrian and the motorist, even though the more intricate designs add substantially to total cost.

In the design of new subdivisions, traffic hazards have been greatly reduced through design and arrangement of minor residence streets to feed naturally into main thoroughfares, but so indirect and inconvenient as thus to discourage all but local traffic movements.

In new large-scale housing projects, the design and arrangement of streets and buildings is such that traffic movements can be confined to the periphery of large unit areas, thus greatly reducing the danger of accident.

6. *Reduction of noise, odors, and other nuisances—*

Zoning has prevented additional nuisances in older residence districts, and has permitted new residence districts to develop without objectionable intrusions, whether or not these are nuisances, *per se*.

The total amount of new building development in cities, most of which has taken place in peripheral areas, covers probably from 50 to 100 per cent more land than was occupied by the older city. This more orderly development of these new sections of the city represents an enormous gain to public health because of the opportunity for living and sleeping in a cleaner atmosphere and with greater freedom from the noise and confusion incident to commercial and industrial activity in close proximity thereto.

One device used in new zoning ordinances, which will probably have wider acceptance in future years, is the regulation prohibiting the erection of new dwellings in industrial districts. Surely it is as reasonable to prohibit new dwelling construction in industrial districts as to prohibit industries in residential districts.

Another type of zoning regulation rapidly gaining acceptance is intended to force gradual elimination of any existing non-conforming commercial and industrial uses in single-family dwelling areas. The number of such non-conforming uses is extremely limited—frequently not more than 1 or 2 per cent, measured either in terms of investment, land area, or total number of buildings. These non-conforming uses invite more traffic than is customary in dwelling areas and this traffic increases the noise, confusion, and the hazards of the neighborhood. Frequently they are objectionable for other reasons. By new planning and zoning measures of this nature we can gradually reduce the conflicts between the commercial and industrial uses and the dwelling areas in our cities.

7. Prevention of slums—

Well planned cities must be economically and socially sound in all parts, not merely in certain sections, such as the high value residence districts. By city

planning we have been able to cut new, wide thoroughfares through the city, establish new playgrounds, and even add new small parks in central areas. The slums are still with us, however. By zoning we have segregated uses of land and buildings by districts, and have established improved standards of light, air, and open space. Zoning applies to new construction only, however. It cannot be used to remove slums. City planning commissions have given much consideration to the slum problem, and have played an important part in the slum clearance and large-scale, low-rent housing program of the federal government. But only the surface of this problem has been scratched. What the form of reconstruction shall be is a city planning problem. Whether these areas are used in whole or in part for new low-rent or for medium-rent housing, for parks, for automobile parking areas, for transportation terminals, for industry, or for other uses, is a matter for determination in each city. This is one of the most important current city planning activities. Plans for reconstruction in the central areas, regardless of its character, must provide for a more balanced design form of the city.

It is the particular function of city and regional planning agencies to see that new slums are not created. New development in suburban areas has not always been of high standard. It is a well known fact that new slums are being created on the outskirts of many cities, due to the absence of building codes, zoning ordinances, and health departments with adequate powers. Many of these suburban areas are unincorporated. County governments are frequently without adequate powers to deal with these suburban slums. Regional planning agencies and city planning authorities are taking leadership in bringing to public attention the dangers of such uncontrolled development. They

have encouraged the passage of county planning and zoning measures and building codes. Within quite recent years several such county planning and zoning acts have been passed.

One of the most effective planning tools in such areas is the adoption and enforcement of land subdivision regulations. Through this device it is possible to require land subdividers to install minimum standards of public services such as an adequate supply of pure water, proper sewage disposal facilities, street surfacing, and lighting, before the subdivision is approved and lots are offered for sale. Other requirements include proper design of the subdivision and the grading of streets and lots, so that the place will become a safe and satisfactory place to live, rather than a new slum. With appropriate planning and zoning, including population density control, these newly developing suburban areas can and should be so designed and controlled as to afford higher standards of urban development than have characterized past practices.

8. *Improvement of recreational facilities—*

A city plan encompasses the whole city, and is designed to meet the specific needs of each part. In congested areas, the lack of open space for recreation is so pronounced that more playgrounds and small parks must be provided. In the reconstruction of slums, the planning agencies expect to require incorporation of such open spaces as part of the basic aims in reconstruction.

One of the standards used in city planning practice is to have a minimum of two acres of playground space at each public school, with not less than 100 sq. ft. of play space per child. In new subdivision plats, these standards are being met. Despite the fact that, in the older developed sections of cities such areas have to be condemned at great cost, much progress in attaining

these standards has been made in recent years.

Another objective in city planning is to have a neighborhood park for each square mile of residential development. In the modern city, solid masses of buildings have spread without interruption over such wide areas that there has been small opportunity for rest and enjoyment of small open spaces amid a bit of trees, grass, and open sky. There is no necessity for such continuous spread of solid building development. We need more open spaces in the form of neighborhood parks than have been provided up to the present time. They are shown on our city plans. Even in neighborhoods of large homes it is now generally the practice in planning to require dedication of open areas for recreational use.

Planning authorities have discussed the advisability of breaking up the solid mass of building development in cities by condemning through them great corridors of open space for purposes of improving the circulation of air, adding numerous recreational opportunities, and relieving monotony. The health value of so doing would be very great. Such corridors could be used most advantageously for vehicular and mass transportation purposes. No violence would be done to the city plans, for distances need not be increased appreciably, and a far better organization of the city would be possible. Only the cost involved and the magnitude of the task have prevented greater acceptance and application of this idea. It can still be done. Here is an opportunity of no inconsiderable consequence for consideration in our post-war program.

9. *Improvement of residential environment—*

Good cities which are well planned, healthful places for normal life, can only be achieved by an alert and active citizenry. We cannot have such citizens

where most of them seek to escape the city. The trek to suburban areas has been motivated in part by a desire for personal participation in the control of environment. In many cases this has been accomplished in some degree in the better type of incorporated suburban communities. Too frequently the individual entertains the belief that this participation in the control of environment is impossible in the large cities. This belief is quite valid. If we are to make large cities desirable places of residence, there must be active citizen participation in the control of environment by local unit areas. The large city must be planned as a composite whole, but it must also be planned by neighborhoods. When citizens can have a part in the control of neighborhood environment, we can make substantial gains in community life.

The St. Louis City Plan Commission has divided this city into some 81 residential neighborhoods and 18 industrial districts. It is the hope that in most of these neighborhoods there can be created a community park and school and a community organization that will

take leadership in the improvement of environment, the fostering of community spirit, and a program of community activities.

Time will not permit fuller discussion of this phase of community planning. In this and other cities the scheme is still in the formative stage. It is mentioned merely because its public health implications are such as to warrant much promise of benefits in the psychological factors of family life and social relationships and responsibilities.

CONCLUSION

This brief attempt to discuss the public health implications in city and regional planning was undertaken without full realization of the magnitude of the task. It is hoped that in other more capable hands the subject may be developed in fuller detail and with greater wisdom. Public health officials have been of great assistance in the field of city planning. Your continued interest and participation will be of tremendous value in planning better cities, in gaining public acceptance, and in aiding official implementation of such plans.

A Small Outbreak of Smallpox in Detroit

FRANKLIN H. TOP, M.D., AND LAURA E. PECK, R.N.

*Division of Communicable Diseases and Epidemiology, Department of Health,
Detroit, Mich.*

IN spite of a known and amply tested preventive, smallpox continues to be reported annually in the United States in shameful numbers. There has been a marked decline in the past decade but there are still too many cases occurring. According to Dauer,¹ for the 20 year period 1900-1919, there were slightly more than 750,000 cases of smallpox reported in the United States. For the next 20 year period 1920-1939, there were 700,000 cases, three-quarters of which occurred between the years 1920 and 1929. The last decade of the latter 20 year period shows a marked decline, but it is interesting to note that the median for the period 1935-1939 was 9,280 cases, a number far in excess of what it should be.

During the interval 1900-1939 a marked change has occurred in deaths attributable to smallpox. The number of deaths recorded during the first 20 year period 1900-1919 was 11,435. For the period 1920-1939 the total deaths were 5,337, of which 90 per cent were recorded between 1920 and 1929. The decline is marked for the period 1920-1939. The favorable change is probably due to the mild type of smallpox (alastrim) now generally prevalent in the United States. According to Chapin and Smith,² alastrim appeared in the United States in 1896, probably having come from Africa to appear first in Florida. Chapin studied the incidence of the classical (severe or malignant)

and of the alastrim (mild) forms of smallpox. The study covered a period of 30 years (1900-1929). The number of cases of alastrim approximated 1,250,000, and during the same interval there were 57,000 cases of the classical type. The fatality rates for the alastrim and classical types were respectively 0.56 and 16.40.

From a study of the trend during the past four decades, it is evident that the severe type of smallpox is decreasing in incidence, and accompanying this decline is a decrease in the number of deaths. Although there is no evidence that alastrim reverts to the classical type of smallpox, the latter is still present and may reappear any time in epidemic form. A large outbreak is possible but not probable on the face of it, but less attention to vaccination and the present rapid change in population groups might prepare the soil for an outbreak or result in an increase in cases and deaths. This possibility is well illustrated by the past experience of Minnesota.³ This state passed an anti-compulsory vaccination law in 1903, and during the first 20 years after it took effect the average annual number of cases reported was 3,000. The public worried little about the situation, for smallpox was mild and few deaths resulted. However, in 1924 malignant smallpox was imported from Canada and a large unvaccinated population was exposed, so that within 20 months

4,041 cases and 504 deaths were reported. As a test of the effectiveness of vaccination a survey showed that only 72 of the cases had previously been successfully vaccinated and only 1 death occurred in this group. Of the remainder (3,969 cases), roughly 85 per cent (3,442) had never been successfully vaccinated, while the remaining 15 per cent gave an indefinite history. Following the outbreak, thousands of persons were vaccinated and during the next 10 years the annual number of reported cases dropped from 3,000 to 225.

It is estimated that between the years 1925 and 1938 some 625,000 infants were born in the state of Minnesota. Many of these infants were not vaccinated because the public had become apathetic again to the necessity for the procedure. To the health worker it was apparent that it would be merely a question of time before the natural consequence of insufficient vaccination would result in a rise in cases and per-

haps an outbreak. The expected rise in cases did materialize. In 1936 the total reported cases of smallpox in Minnesota was 397; in 1937, 671; and in 1938, 859. There was a decrease in 1939, however, the total being 492. Whether this favorable lessening of cases will continue, only time will tell.

Michigan's experience has been similar to that of Minnesota except for a rise in 1939 rather than a decline. The total cases for Michigan were lower: 118 in 1937, 365 in 1938, and 615 in 1939.

In general, the average annual case rates for smallpox have been very low in the eastern states, particularly in the New England, middle Atlantic, south Atlantic, and the east south central states. The highest rates have been noted in the east north central, west north central, mountain, and Pacific states, with somewhat lower rates in the west south central states.

The State of New Jersey with a popu-

lation of 4,400,000 reported not a single case during the period 1931 through 1938, while the States of North Dakota, South Dakota, Montana, Idaho, Oregon, Wyoming, and Utah, with a combined population similar to that of New Jersey, reported 12,666 cases during the same period. Three states in the above group prohibit compulsory vaccination by statutory regulation regardless of prevailing circumstances.

Table 1 shows the number of reported cases of smallpox in the United States during the years 1920 through 1941. Marked variations are noted in the number of cases by individual years. In 1920 there were 110,700 cases, but by 1922 the number had dropped two-thirds. The deaths from smallpox in 1920 were 490 but in 1922 the number was 900. A study of the table will show fluctuations from year to year in the case column. From 1924 on, the number of deaths decreased progressively; exceptions are 1929 and 1930 and 1936 to 1940, the number of deaths recorded for these periods exceeding the years just preceding.

Table 2 shows the incidence of smallpox in the period 1932-1941 in relation to state vaccination laws. In states where vaccination is required as a prerequisite to school attendance, the average annual case rate per 100,000 of the population was in every instance under that noted for the 7 states where compulsory vaccination is prohibited by law. The average annual case rates for the latter states is more than 13 times greater than the average for the group where vaccination is prerequisite to school attendance.

LOCAL INCIDENCE OF SMALLPOX

The incidence of smallpox in the City of Detroit for the period 1920-1941 is shown in Table 3. It will be noted that this city had two large outbreaks in the interval. One occurred in 1920 with 1,125 cases and 4 deaths. The smallpox

Annual Case Rates were calculated from data in Table 2, Dauer: by H. E. Pearson, Department of Epidemiology, School of Hygiene and Public Health, University of Michigan.

during this outbreak was the alastrim type, but the smallpox encountered in 1924 was more severe and, according to Dr. Henry F. Vaughan, Health Commissioner of Detroit at the time, it appeared that both alastrim and the classical types of smallpox were occurring at the same time. It is certain that the classical type was represented and by its worst form, hemorrhagic smallpox. Every person developing the hemorrhagic type of smallpox expired. In 1924 there were 1,610 cases and 163 deaths. From 1924 on, the annual number of cases was less than 100, with the

1941	6	0	0.0004	0.0	0.0

exception of 1930 when 151 cases were reported. Beginning with 1932 there have been 5 years with no cases reported, and from 1926 on no deaths have been recorded. The case incidence has been low since 1932, the highest number reported in the period has been 15, noted in 1937 and 1940.

DATA—SMALLPOX OUTBREAK, 1940

Small outbreaks still occur from time to time as amply demonstrated by the experience in the state at large, and by the following occurrence of cases noted in Detroit during the fall and winter of 1940-1941. The cases listed in Table 4 comprise a group of persons with smallpox and are listed in sequence according to their discovery. The listing includes sex, age, date of diagnosis, date of rash, vaccination status, diagnosis, date and by whom diagnosed. In the column "remarks" will be found data which served as clues to the solution of the occurrence of smallpox among a rather widely scattered number of cases and served also to uncover likely cases which had occurred previously but which

verified except by history of contact.

The first case, G. F., came to the attention of the Health Department when the occupants of the upper portion of an income bungalow asked for instructions with respect to their exposure to the owner of the dwelling who had a rash. The owner had been ill at home with what had been diagnosed as chicken pox and had on several occasions, while ill, used the telephone of the upstairs occupants. The latter had become suspicious that the rash might not be chicken pox. Upon investigation smallpox was discovered in 4 members of the family.

The probable sequence of cases which are connected to one another by definite contact and shown by interval, well within the limits of the incubation period, is shown in Table 5 and Chart 1.

The first case in the series to come to the attention of the Health Department was discovered on December 11, 1940, almost 2 months after the so-called first case. The source of infection in C. P. (1) could not be determined and she

CHART 1—Smallpox Outbreak in Detroit, 1940
Probable Source of Cases Showing Age and Date of Rash

COMMENT

The outbreak occurred principally in families closely related by blood but all the families involved were not on good terms with one another. It was difficult to get reliable information. First, because the affected individuals did not believe they had smallpox and second, the persons involved knew that restrictions for smallpox were far more stringent than for chicken pox. Repeated

visits to the F. and P. families resulted in the discovery of the case A. K. (6) who was really responsible for several of his school mates contracting the disease, two of whom each gave rise to one additional case. The K. family did not tell the same story twice and only on threat of severe restriction for all members (remainder of family previously vaccinated and had good scars) would they implicate others.

* Actual sequence number

No case in this outbreak had previously been successfully vaccinated. Mr. F., father of the F. family, had been vaccinated many times previously without a successful take. In the F. family (6 members) the only person to escape the infection was a son aged 14 who was successfully vaccinated at school in 1937 and who showed a good scar. In

the K. family (5 members) the only person to contract smallpox was the unvaccinated member, a boy of 6 (case A. K. (8)).

The outbreak was slow in evolution, attesting to the mildness of the disease. In the P. family there were 3 cases in sequence at intervals of 2 weeks apart. The F. family group, 6 cases (including

J. H. (9)) occurred in the following sequence: 1—1—3—1.

Actual sequence Cases 1, 4, 5, 6, and 7 were seen by a physician and diagnosed chicken pox. Case 3 was seen by a chiropractor and diagnosed chicken pox. Cases 3 and 8 were not seen by a physician. Again, the first cases in the F. family (cases 4, 5, 6, and 7) were all seen by the same physician on the same day and diagnosed chicken pox. No subsequent calls were made by the physician and had the patients been seen at a later date it is possible that the real condition would have been diagnosed. G. F. (6) could not have been lightly mistaken at the end of the first week of the rash. He felt quite ill and was confined to bed. His wife, E. F.

(7) had few symptoms, relatively few lesions, and was up and about throughout the course of her illness. Patient A. K. (8) had no more than 20 lesions, well scattered and crusted when seen, but the lesions were shot-like to the touch and suspicious looking. The relative mildness of the infection and paucity of the lesions in some instances made a diagnosis of smallpox on one visit difficult to make.

Integration of Medical Care into the Health Program in Rural Missouri*

J. W. WILLIAMS, JR., M.D., M.P.H.

*Director, Local Health Administration, State Board of Health,
Jefferson City, Mo.*

IN many urban communities, serious and partly successful efforts have been made to administer services of medical care for indigents and for the low income group. In rural areas, however, this is essentially an unsolved problem and the experience in Missouri is offered as of possible interest and aid to others working under somewhat similar conditions.

In order to understand developments in this state, it is necessary that certain fundamental legal provisions and limitations be set forth. As is the case in many southern states, the county courts are in reality the business agents for the counties. They conduct financial affairs and determine appropriations for all matters, including public health and medical care. They sit as a judicial body only when indigents come before them for commitment or admission to state institutions: hospitals for the care of the insane, feeble-minded, cancer, tuberculosis, and orthopedic conditions. Of great importance is the fact that the care of the indigent sick, by statute, is the concern of the county court. Section 9590, Revised Statutes, 1939, reads as follows: "Poor persons shall be relieved, maintained, and supported by the county of which they are inhabitants." Because of this

legal requirement, because of the qualities inherent in a situation where one is ill and without care, and because of popular demand, the care of the sick is of much greater concern to the county courts in Missouri than is the problem of preventive medicine, and if placed in the position of a county judge who depends for his job upon the support of the electorate, most of us would take the same stand that he does.

The majority of counties, therefore, have attempted in the past to meet this obligation one way or another, usually by the appointment of part-time county physicians, and by court action to decide which cases are to be seen by the county physicians, which may go to hospitals, and length of hospitalization for which the county will pay in each individual case. It is obvious that under such a system medical care might be efficient here and unsatisfactory there, or excessively costly in some counties with practically no expenditures in others, these things depending on the custom of the individual county, its financial ability to pay for the service, and on other factors.

For all practical purposes the county revenue is derived only from taxation of real estate and personal property. After the assessment has been made the court fixes the tax levy. However, the maximum levy in any county is set by the State Constitution, so that the available funds for county opera-

* Presented before the Health Officers Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

tion are definitely limited and can be easily determined. The maximum rates per \$100 valuation that can be levied for all purposes depends upon the total assessed valuation of the county and are as follows:

<i>Counties with Valuation:</i>	<i>Per \$100 may levy</i>	<i>Counties Assessed in Valuation Group</i>
0- 5,000,000	\$.50	21
6,000,000- 9,000,000	" " .40	14
10,000,000-30,000,000	" " .50	68
30,000,000 and over	" " .35	11

To complicate the matter further, there exists a state-county budget law under which each county must conduct its financial business. The county budgets are prepared annually by the county court upon the basis of anticipated revenue. This is estimated by applying the tax rate set by the court against the total assessment. The budgets must be made up and all expenditures made according to six classifications, and in the following order:

1. Maintenance of county patients in insane institutions
2. Cost of courts and elections
3. Repair and maintenance of bridges on other than state highways
4. Salaries of elected officers, their deputies, and office supplies
5. General
6. Repairs, replacements, equipment

By the time the expenditures necessary to maintain the first four classes are allotted, little money remains in class five from which all county functions, not listed in the four preceding classes, must be maintained. It then becomes obvious that the average county, under existing tax laws, cannot support two health services, one curative and the other preventive, and where only one service can be provided it naturally is the curative.

To meet the situation there grew up in some of the county health units a feeling of responsibility for the medical care of the indigent population for which nothing was being done, and

their programs gradually changed to include general medical clinics, obstetrical service, hospital care, special clinics such as eye, ear, nose and throat, and medical care of the inmates of the county jail and county farm. In such a program, the county health unit not only served as the central administrative agency of all health activities within the county, but the health officer soon became the medical adviser to the county court and to other elected officials. The medical decisions were made a responsibility of the health officer rather than of the county court. The first one of these units so to function developed in 1925, the second in 1930, and in both of them the health officers actually did the medical work themselves until the depression years forced the addition of part-time medical assistants to the staff. Neither of these units, however, has ever had adequate personnel to render completely satisfactory services in all branches.

Realizing that the development of new units was dependent upon availability of funds and that only limited county funds were available, and recognizing further that medical care came first with the county judges, state assistance to counties was increased and combined medical care and health programs were urged. The present maximum tax levies permitted the counties by law make it impossible for the 35 counties with valuation of less than 10 million to contribute 50 per cent of the cost of a four piece unit, and only counties of at least 20 million assessed valuation can supply 50 per cent of the budget of a combined unit. More people are required to conduct a combined program but usually medical aid on a part-time basis has been obtainable and has been satisfactory. When one of the larger counties was approached regarding the development of a health unit the answer was that no funds were avail-

able. Upon investigation of county records, however, it was found that the court had been expending \$12,500 annually on indigent medical care, given by 2 part-time physicians, plus drugs and hospitalization under direction of the county judges. The court was again approached on establishing a combined unit using their \$12,500 budgeted for medical care to which was added \$10,000 state assistance, which they accepted. These two funds totaling \$22,500 then provided the county with a full-time health unit. The personnel consisted of a health officer, 4 nurses, engineer, clerk and the same 2 physicians as part-time assistants. The unit was housed in a building of its own with ample space in which to conduct all its program.

Many times the question has been asked if public health did not suffer in such a program. The answer is yes, but the county had no health services at all before organization of the unit. To answer the question of how much time was devoted to medical care, a short-time study was recently made in three units (Greene, Jasper, and Laclede Counties) to determine the proportion of time spent by the entire staff on administration, on conventional public health activities, and on medical care. These three counties were selected because of differences in the age of the units, size of the staffs, and their location. The Greene County Unit was established in 1925. The county's population of 29,303, surrounds a city

of 60,000. The unit's program includes residents of the city in venereal disease and tuberculosis control (see Table 1).

TABLE 1

Population and Per Capita Budget

	<i>Population 1940</i>	<i>Total Budget 1943</i>	<i>Per capita Budgeted</i>
Greene	29,303	\$28,130.00	0.958
Jasper	30,979	25,440.00	0.820
Laclede	18,718	18,450.00	0.985

The Jasper County Unit was established in 1940. It serves a population of 30,979 outside the limits of two municipalities of 37,144 and 10,585 population, but includes control of venereal disease and tuberculosis within the two cities. These two counties are, therefore, similar in many respects.

Laclede County by way of contrast is or was a purely agricultural community of 18,718. The largest town in the county has a population of 5,000. The establishment of Fort Leonard Wood in the adjoining county created new problems for Laclede County and resulted in the establishment of the county unit in 1941.

The personnel making up these three units naturally varies in number (Table 2) with the population served and increases apparently as the age of the unit increases.

The time studied was a 2 weeks period, September 21 to October 5, 1942. The units were visited on Friday and requested to begin the study the following Monday to prevent change in the program that might have influenced the distribution of time if the study was

planned in advance. Each unit made an independent time study and reported the activities during this period. A summary of the time spent in administration, purely public health such as venereal disease, tuberculosis, preschool conferences, etc., and on medical care by all the professional staff revealed a surprisingly small percentage of time going into the medical care program (Table 3).

Medical care required from 4.8 per cent in Jasper County to 12.8 per cent in Greene County exclusive of travel time, while time spent on purely public health activities varied from 39.2 in Laclede County to 64.27 per cent in Greene, exclusive of travel. Since the time of the sanitation officer would necessarily weigh the figure in favor of purely public health, his time was not counted, and the total time spent by the health officer, part-time medical staff, and the nurses on medical care was studied but changed the time distribution relatively little, approximately 2 per cent (Table 4).

Although the time spent on medical care by the whole staff was a relatively small percentage of the total, the question of what was happening to the

health officer himself was considered. But here again the time spent by the administrator in actually giving medical care was comparatively small, being 7.3 per cent in Jasper, 9.1 in Greene and in Laclede 19.46 per cent, exclusive of travel (Table 5). Administrative duties consumed from 16.8 per cent in Laclede to 46 per cent of the health officer's time in Jasper County. Nursing time devoted to medical care is very low, varying from 2 to 8 per cent (Table 6), and this was usually spent in clinics (Tables 5-6).

It would appear that the age of the unit has a definite influence on the distribution of time spent in the three activities. The older the unit the less time spent on administration and the greater the time put into purely public health services and into the medical care. In the younger units relatively more time is spent by all personnel on office routines and less on public health and medical care (Table 3).

The time consumed in total travel would seem to be somewhat influenced by the age of the unit but the difference found between the three units is small. The time spent in travel while rendering medical care consumed only 1 to 2 per

TABLE 4

Percentage of Time Distribution by Medical and Nursing Personnel

	Administration		Public Health		Medical Care		Total	
	Service	Travel	Service	Travel	Service	Travel	Service	Travel
Greene	5.6	0.08	63.75	14.6	14.60	1.37	83.95	16.05
Jasper	15.3	1.8	58.50	17.5	5.7	1.20	79.50	20.5
Laclede	26.53	1.16	42.41	17.46	9.66	2.80	78.60	21.40

cent of the total travel while purely public health travel used 14 to 17 per cent of the total time.

Although the units' activities were being surveyed to find out what and how much the medical care part was taking away from the public health program, a report was requested from each of the units on the regular monthly report form (B-1427) for the study period. A review of the services rendered would seem to indicate that all phases of the health program were touched, and that there was no evidence that any part of the program of general health had been slighted for another, although the study period was very short and the sample may not be considered good.

After seventeen years' experience with an integrated public health and medical care program in one unit and twelve years' experience in another, the results have seemed to warrant the courts being advised to establish new county units on this basis. There are now six of them in full operation in rural areas. This course has been deemed wise in view of the fact that county funds are limited by statutes and by the Constitution, and generally are too small to pay for two local health services. Since the county courts are definitely responsible for providing some medical care program, it becomes essential to establish the integrated program under the administrative direction of the full-time health officer, if health units are to be developed throughout the rural areas. The cost of the combined programs is, of course, more than the cost of the usual type. The three units under study cost an average of \$.92 per capita which is more than usually provided for rural local health

work. However, in general it has been found that the previous cost of medical care alone to the county is sufficient to meet the county's part in maintenance and operation of the combined unit under the direction of the health officer. The budgeted amounts per capita in Greene and Jasper Counties are not a fair evaluation of cost, since venereal disease and tuberculosis are cared for in the total municipal as well as the county population (Table 1).

None of the units conducting the combined program has ever had a staff sufficient in number to render complete and adequate medical care and corrective dental programs. They have, however, delivered good services, superior, it is believed, to the medical services rendered under the administration of a county judge or by a part-time county physician without the guidance of a full-time health officer. The services rendered in all fields of health both preventive and remedial have demonstrated to the community, by actual care of the sick and injured, the importance of the total health service which the purely public health activities, by their very abstractness and intangible nature, could not possibly have done.

It is now felt that in Missouri we have definitely passed through the experimental stage. We believe that a combination of medical care and public health service is practicable, in that a combination unit under the single administrative direction of the health officer offers a unified service satisfactory to the court, and supplies the community with both curative medical care and preventive service which is within the power of the tax payer to support.

Errors in Clinical Statements of Causes of Death

Second Report *

KURT POHLEN, PH.D., AND HAVEN EMERSON, M.D.,
F.A.P.H.A.

*Consultant in Statistics, W. K. Kellogg Foundation, Battle Creek, Mich.†;
and Professor of Public Health Emeritus in Residence, DeLamar Institute
of Public Health, College of Physicians and Surgeons, Columbia
University, New York, N. Y.*

THIS is the second paper of a series on "Errors in Clinical Statements of Causes of Death." In using the word "error," we do not necessarily mean real or serious diagnostic mistakes such as occur when, for instance, the clinician diagnoses an ulcer of the duodenum which proves at autopsy to be a carcinoma of the stomach, or when the pathologist finds that the aneurysm of the aorta is not due to syphilis, but to arteriosclerotic degeneration.

Besides such incorrect statements we often find others which are only incomplete diagnoses; for instance, if "pneumonia" is stated instead of the precise diagnosis, lobar pneumonia or bronchopneumonia. In this group of partly correct statements belong cases in which the clinician has given only the site or pathologic condition, or both, secondary to the primary disease. This is especially true with metastasis of malignant tumors, and purulent infections.

Both such groups of diagnostic errors, the incorrect and partly correct statements, are of a *clinical nature*. Comparing the clinical diagnosis with the autopsy findings, we are in most cases in position to decide whether the clinical diagnosis was correct, partly correct, incomplete or incorrect. But dealing with the statistics of causes of death, we frequently find differences between clinical and pathologic causes of death as they are to be tabulated according to the *International List of Causes of Death*.

For instance: A case in which the clinician has given the cause of death as "hypertensive arteriosclerotic heart disease" and the pathologist reports: "nephrosclerosis with hypertension and myocardial failure," we decide that the clinical diagnosis is correct because the same condition was meant in both diagnostic statements. The classification of these two statements according to the *International List of Causes of Death*, however, would place the clinical diagnosis under No. 93d (hypertensive heart disease when no involvement of the kidneys is mentioned) and the pathologist's statement under 131a, because the arteriosclerotic kidney is mentioned. Thus, we find the same clinical condition may be tabulated under two

* Based upon 25,066 clinical and post-mortem statements on causes of death. The Tables 1-5 contain only an abstract of 19 diseases, the complete tables refer to every disease listed in the *International List of Causes of Death* with numerous additional subdivisions. The first report appeared in *A.J.P.H.*, 32, 3:251 (Mar.), 1942. The final report, to be finished in 1943, will be based on 40,000 autopsy protocols and clinical histories from 30 different hospitals.

† Recently of the Bureau of Vital Statistics, New York City Health Department.

different rubrics or numbers of the *International List*. In another illustration, we find the opposite situation: when the clinician, without having made an operation or biopsy, diagnoses a carcinoma of the gallbladder and the pathologist finds a sarcoma of the liver with obstruction of the biliary passages, we have a clinical error of site and kind of disease. Tabulation of either statements would, however, be under the name number, 46f (cancer of the liver and biliary passages).

The first example is complicated by the lack of uniformity in clinical diagnoses and terms of the *International* classification and brings both statements "arteriosclerotic heart disease" and "hypertensive cardio-vascular disease" under the same number, 93d (chronic myocarditis without mention of rheumatism), but the clinician means, in most cases, renal involvement when he states the condition to be that of hypertension. Of a similar nature are all cases where the clinician states: "chronic rheumatic cardio-valvular disease" without mentioning especially that the mitral valve is also affected. These cases must be registered under No. 92c (chronic myocarditis, specified as rheumatic). The pathologist gives accurately the same diagnosis, but mentions in his report aortic stenosis and insufficiency, mitral stenosis and insufficiency and many secondary conditions caused by this "chronic rheumatic cardio-valvular disease." The result in tabulation is to list that case under 92b (chronic diseases of the mitral valve). We find later that the bulk of changes in clinical and pathologic assignments to numbers of the *International List* for cardio-valvular and cardio-vascular diseases are due to such lack of uniformity of diagnostic statements.

We have to mention the only further important source of changes in the statistical tabulation caused by different assignment according to primary and

contributory causes of death. We have in this group two possibilities:

(a) cases in which both diseases, which occurred simultaneously, have been diagnosed by either clinical or post-mortem examination, but where the clinician was of other opinion than the pathologist, as to which disease shall be mentioned as primary and which as contributory.

(b) cases in which the disease, mentioned solely by the clinician, was verified by the pathologist, who, however, found an additional or other condition of primary importance. We have, for instance, several cases of benign hypertrophy of the prostate (No. 137a), in which the clinician found beside the benign hypertrophy a carcinoma of the prostate and mentions the malignant tumor in first place as primary cause of death, and reports both conditions as the final causes of death.

It is sometimes extremely difficult to decide whether or not the clinician made a mistake, especially in cases belonging to group (a), and more so when the pathologist says afterward that the clinical opinion is correct also.

The comparison of Errors in Clinical Statements, as they appear in the statistics of causes of death, must therefore consider both types of diagnostic changes of:

- (I) clinical nature
- (II) statistical tabulation

Such a twofold and combined consideration of incorrect, incomplete, partly correct, and correct clinical statements is the subject of this second contribution.

Our first objective is to determine the accuracy of clinical statements with regard to the clinical nature of the diagnosis. Every complete diagnosis consists, or should consist of three statements:

- (1) the cause of the disease
- (2) the organ which is affected
- (3) the manifestation and pathologic changes caused by the disease

Illustration: "ruptured appendicitis" is complete; it gives the organ (appendix), the cause (infection), and the pathologic condition (rupture). "Arte-

riosclerotic cardio-vascular disease" is incomplete; it gives the organ (cardio-vascular system in its entirety), the cause (arteriosclerotic degeneration), but it fails to give the important manifestation which may be that of a coronary sclerosis, nephrosclerosis, cerebral hemorrhage, etc.

In the first report we did not attempt to evaluate the clinical statements regarding the manifestation of diseases, because of the difficulties due to lack of uniformity in diagnostic definitions, especially as far as the pathologic verification of clinical statements is concerned. We have, for instance, to remember that some manifestations of disease, removed by operations, cannot be seen at autopsy. Second: In this paper we intend to compare the results of the statistics of

causes of death with clinical considerations which must be based upon the statistical classification of diseases in which only occasional manifestations are mentioned (such as cholecystitis: with and without mention of cholelithiasis, the arteriosclerotic cardio-vascular and the rheumatic cario-valvular diseases, and the manifestations of tertiary syphilis, etc.)

We have, however, distinguished in each case, between the *site* of disease and the *cause* of disease, and coded each clinical statement according to the degree of its correctness or incorrectness, topographically and etiologically.

The following code was used for diagnostic changes which are numbered from O to Y in twelve different items with corresponding meanings for the topo-

CODES FOR DIAGNOSTIC CHANGES

	Code	Topographic	Etiologic
Correct	0	(the statement is considered correct also in cases where the body as a whole is affected, or the correct site was not found in either diagnosis)	Correct cause is stated (the statement is considered correct also in cases where in neither diagnosis a specific cause but only a pathologic condition has been given)
Incomplete	1	Only correct organ system or body system was mentioned	Only correct etiologic or pathologic group was mentioned
Partly Correct	Specified Diagnosis	2	Secondary area involved in extension of disease has been mistaken for primary site
		3	Secondary site (metastasis or other secondary lesion) has been mistaken for primary site
		4	Site of contributory disease, which is independent of primary disease, has been mistaken for site of primary disease
		5	Organ system or body region of secondary site, which is different from organ system or body region of primary site, has been mistaken for primary site.
Unspecified Diagnosis		6	Organ system or body region of contributory disease, different from organ system or body region of primary disease, has been mistaken for site of primary disease
		7	Incorrect specified site, belonging to the same organ system of correct site and in close topographic relation
Incorrect		8	Other specified incorrect sites
		9	Incorrect unspecified site, belonging to another organ system or body region
No diagnosis		X	Only a symptom or manifestation, not indicating a definite disease (cause) is mentioned
		Y	No site of primary disease is given

graphic and etiologic part of the diagnosis.

0—means a correct diagnosis, where the pathologic statement is the same as the clinical statement.

1—means incomplete statements, such as pneumonia instead of lobar or bronchopneumonia, or urinary infection, etc.

2—indicates the secondary area (or pathologic condition, etiologically) involved in extension of the disease. These are cases in which the form of the lesion (manifestation) plays its part, and to which a complicating extension of the process, e.g., a carcinoma of the prostate, involving ureters and bladder belongs.

3 and 4—distinguish the secondary and contributory diseases, the former caused by the primary disease and the latter independent of it.

5 and 6—are similar to 3 and 4, respectively; in 5 and 6 the site or cause is not given in precise but rather in unspecified terms, for instance, tumor of the urinary system.

The other items are self-explanatory.

A code number 00 means that the clinical diagnosis was correct, topographically and etiologically; 10 means: incomplete topographic and correct etiologic statement (e.g., the beforementioned example of pneumonia); 01 means: correct topographic, incomplete etiologic statement (e.g., tumor of prostate instead of carcinoma or benign hypertrophy of the prostate); 24 means: secondary site and contributory disease (e.g., a case of carcinoma of the stomach with metastasis in the liver diagnosed as liver cirrhosis when the liver cirrhosis was really present), but a case of carcinoma of the stomach without metastasis in the liver, diagnosed as liver cirrhosis, when cirrhosis of the liver was present, would be coded as 44; 88 means: a disease incorrectly diagnosed both topographically and etiologically.

This large number of different code numbers is summarized in our report according to the group mentioned in the first column: *correct, incomplete, partly correct, incorrect, and no diagnosis*.

We may refer first to *Tables 4 and 5**

dealing with 19 diseases of interest, according to frequency, statistical consideration and for other reasons. The tables are based upon slightly more than 25,000 cases; the final report will deal with more than 40,000 cases. Our preliminary study includes each disease mentioned in the *International List of Causes of Death*. Since these 5 tables and additional figures referring to a former similar study made upon material from Magdeburg contain 115 pages, we have summarized our results in the material presented here.

Table 4 refers to the accuracy of topographic statements, disregarding the etiologic statements, and *Table 5* to the accuracy of etiologic statements, disregarding the topographic part of the diagnosis. We find 6 per cent of cases with incorrect site of disease, and 10 per cent with incorrect cause of disease. The frequency varies among the diseases considerably, as we see in column 12.

Column 10 indicates the percentage of contributory sites, or causes, taken as primary causes, and column 5 gives the results of the positive part of our study, the correct sites and causes, which are, about equally, slightly more than four-fifths of all cases.

Table 3 combines the accuracy of statements regarding the clinical nature and the comparison of statistical tabulation for the same diseases. We have, at first, divided all cases whether or not the clinical diagnosis was correct, incomplete, partly correct, and incorrect (including with the latter group the cases with no diagnosis given). Under incorrect are included all cases in which either part of the diagnosis was incorrect; i.e., that incorrect site but correct cause, or vice versa, renders the whole

* The tables are numbered according to the sequence of the complete tables contained in Vol. 2, Nos. 4 and 5, of "*Health and Statistics*," published by Kurt Pohlen. A limited number of copies of these tables are available to those interested.

diagnosis incorrect. Similarly, we defined as partly correct all cases in which at least one part of the diagnosis was partly correct, the other part may be better (incomplete or correct) but not incorrect, and so forth.

Then we distinguished in every group of "correct, incomplete, partly correct, or incorrect" diagnosis the individual cases, whether or not the respective number of the *International List* was the same, if tabulation was made on the clinical diagnosis as it would have been had the pathologist's statement been used as basis of tabulation.

In column 6, for instance, 190 cases of chronic rheumatic endocarditis (No. 92c) are mentioned, where the clinical statement "rheumatic chronic cardio-valvular disease" was considered correct, but where the additional findings at autopsy revealed the mitral involvement and called for a different classification under 92b. The same is true with the disease No. 93d, chronic myocarditis, not rheumatic, where beside 278 correct cases there were 265 others, mostly "hypertensive cardio-vascular diseases" for which their international classification was changed due to insufficient definition of the disease.

Table 3 is based upon the clinical diagnosis; all diseases being first sorted according to the *International List* numbers of the clinical statement. Then they were grouped according to the code as correct, incomplete, . . . etc., diagnoses.

We can carry out the same operation in sorting all cases under the *International List* number according to the pathologist's statements and consider how many of them were previously (at clinical examination) correctly, incompletely, etc., diagnosed.

This is done in *Table 2*, which is arranged in the same manner as *Table 3*. We see here again two diseases with large frequencies in column 6, but now No. 92b, chronic diseases of the mitral valve, and 131a, arteriosclerotic kidney,

to which the corresponding cases of chronic rheumatic endocarditis, and chronic myocarditis, beforementioned, were transferred. It is not a mere coincidence that we find in column 6 of *Table 3* (under disease No. 92c), and in column 6 of *Table 2* (under disease No. 92b), exactly the same number of cases.

The final figures for vital statistics, summarizing the experience of *Tables 2 and 3*, are given in *Table 1*, which refers to the classification according to the *International List of Causes of Death* only. Let us take, for illustration, No. 46b, cancer of the stomach. The clinical examination resulted in 555 cases classified under this rubric, of which 456 (col. 6) were verified by autopsy, which means that the pathological classification was the same for them. In 99 cases, however, their allocation in the *International List* was changed, 24 times due to incomplete or partly correct statements and 75 times due to real diagnostic errors.

In addition to the 456 cases of clinically diagnosed and pathologically verified cancer of the stomach, there are 168 cases in which the gastric malignancy was discovered at autopsy only; 90 times among them due to incomplete and partly correct statements, and 78 times due to an incorrect diagnosis. This gives a total of 624 cases, which is 12 per cent higher than the figures compiled according to the clinical examination.

The rate 12 per cent is listed in column 12 as coefficient of correction, which indicates the percentage to which the figures based on clinical statements must be increased or decreased when corrected by the figures based on the pathologist's statements.

In columns 10 and 11, are listed two types of indices of error. If we take again the example of carcinoma of the stomach, we find that this disease (or a disease which has the same *International*

	Total	25,066	67	16,782	836	161	747	163	2,910	46	3,391			

number) was mentioned in 723 cases:

- 456 times in both the clinical and pathological statement,
- 99 (24 plus 75) times in the clinical statement only, which was not verified by autopsy, and in
- 168 (90 plus 78) times in the pathologic statements and not previously mentioned as any kind of gastric malignancy in the clinical record.

Among the 723 cases, in which some kind of gastric malignancy was mentioned, we find 456 correct and 267 (99 plus 168) erroneous statements. These 267 erroneous statements are 37 per cent of the total of 723 and this can be considered as the Index of Error.

Based upon our studies on the difference between incomplete, partly correct, and incorrect diagnoses, we may divide the Index of Error into

(a) the error of clinical diagnosis (col. 10) which includes both types of incorrect diagnoses (75 clinical statements not verified post-mortem and 78 post-mortem statements not observed clinically), and expresses the sum as a percentage of the total of all examinations in which cancer of the stomach is mentioned.

(b) the inadequacy of statistical tabulation (col. 11) which combines in the same manner the changes in the *International* classification due to incomplete and partly correct statements.

The variation of the Indices of Error is seen in *Table 1*. We observe the large difference between the infectious diseases (scarlet fever, tuberculosis of the respiratory system, and measles) and the organic heart diseases (endocarditis and myocarditis), but we see also the large factor of partly correct diagnoses among the latter.

These facts cannot be discussed in detail here. We mention briefly, however, the two other groups, representing the data from *Tables 4 and 5* and indicating the accuracy of etiologic and topographic statements, separated from each other.

Statistical studies like these about

which we are reporting cannot be easily compared with other similar studies. This is due to several causes:

(1) Our present material is derived from outstanding hospitals. We might expect to find here relatively low "Indices of Error," but we have seen that the statements of the best clinicians by reason of their exactness and completeness of diagnostic statements differ often in some details from the findings of expert pathologists. The better the pathologic examination, the higher the per cent of error.

(2) A nomenclature of diseases which goes into many details makes more changes in the statistical classification possible than a nomenclature which is less detailed. For instance: the previous *International List* (1929) mentioned chronic nephritis only. Today (1938 list), we have a division into arteriosclerotic kidney and other chronic nephritis. Numerous cases of chronic glomerulonephritis which proved to be arteriosclerotic kidney are, in the present study, considered to be incorrect diagnoses; they did not indicate a change in the statistical tabulation before the last revision of the *International List* took place in 1938.

CONCLUSION

We recognize that we all are inaccurate, partly because we do not have the means to establish and express the truth completely. There are inaccuracies in vital statistics, but we do not think that vital statistics are therefore worthless or should be discarded or unused. On the contrary, by identifying the location and degree of errors, we are in the position to offer valuable aid to the clinician and the pathologist in diagnosis, and we increase the information which statistics can offer by making manifest those errors which so often are used to discredit vital statistics. In this way, the former cause of unreliability becomes a source of genuine information.

The statistics which we have presented herewith and those presented last year would be incomplete if we should not have tabulated the direction of diagnostic changes. Now we know how often a diagnosis has been incorrect, but

we do not know yet which new diagnosis took the place of the one first given. We are, therefore, preparing tables that show each individual change of diagnosis and all combinations of diagnoses with each other.

We are preparing to make the same (or similar) tables as for the clinical and pathologic cause of death, for the comparison between the diagnosis at admission to hospital and at autopsy. Furthermore, we are sorting our records

according to cases with operation, biopsy, electrocardiogram, etc.

Finally, we are preparing tables giving the combination between primary and secondary conditions, on one hand, and the various contributory diseases on the other hand (each separated from the other). These tables based upon autopsy findings, will then include the various secondary conditions and manifestations in order to give a complete picture of the cause of death.

Simplified Procedures in Tuberculosis Control

H. R. EDWARDS, M.D., F.A.C.P., AND
A. B. ROBINS, M.D., DR.P.H.

*Director, Bureau of Tuberculosis; and Supervisor of Clinics, Bureau of
Tuberculosis, Department of Health, New York, N. Y.*

EVERY tuberculosis administrator, health officer, and worker in the tuberculosis control field will be faced with greatly increased problems from this time forward until more nearly normal conditions are restored in the world. A large number of physicians, nurses, and other trained personnel are now serving this country in the armed forces, and more will follow in the coming months. At the same time there is evidence to show that since 1938 the rate of decline of the tuberculosis death rate has been definitely slowed. The rise of tuberculosis in Great Britain and other countries directly involved in the war should be a warning to this country, for in a large degree the same problems of reduced standards of living will become operative here as there. This problem of more to be done and less to do it with will demand a more realistic and practical program than has been followed by many in the past.

If the traditional procedures used by many clinics for years in clinic supervision are continued, it can only result in a greatly increased case load per unit of physicians' or nurses' time. Up to a certain point this may be absorbed, but if exceeded the individual handling of the case can only be maintained by longer working hours of the staff, or by the elimination of unproductive routines, thus releasing more professional

time for the really significant case. There can be no debating the point that whatever plan is used, it must be efficient and effective. The physicians who remain will find their other duties increased as well as those in the clinic, so that more time in the clinic will become more and more difficult to provide.

The need for such simplification of procedure has confronted the Bureau of Tuberculosis in New York City for many years, and considerable effort has been given to analyzing the productivity of our procedures. As a result, over the past few years we have made a number of changes which may appear radical to others, but which have in our experience greatly expanded the effectiveness of our staff, with no sacrifice of expert attention for the individual case.

The success of these procedural changes is best illustrated by an analysis of the volume of our work. In an 8 year period, from 1933 to 1941, there has been an increase of 70 per cent in the number of individuals seen in our regular clinics. During the same time the number of clinic visits increased only 26 per cent. It has been in part this saving in visits that has permitted the clinic staff to accommodate the greatly increased case load and still provide more effective service to the individual patient. During the period covered by the fiscal years 1938-1939 to 1940-

1941 the number of physicians' sessions has remained almost constant, despite the fact that there was an increase of 11 per cent in new individuals examined in the regular clinic, and an increase of over 90 per cent in the number of individuals examined in mass surveys.

These simplified procedures have been arrived at through analysis of our clinic activities, special studies of specific problems, and review of the experience of other workers in the field. Most important, they have been based on consideration of the fundamental philosophy underlying clinic tuberculosis control activities. This calls for acceptance of the fact that it is not humanly possible so to supervise all contacts, much less all so-called susceptible individuals in the community, that all lesions will be detected in their incipient stages. Furthermore, it also calls for the realization that medical examination and routine supervision of exposed or susceptible individuals will not of itself prevent the development of a lesion. At best, periodic supervision can only hope to detect a lesion in its earliest phase. We have had occasion to observe that some cases will develop lesions in spite of close supervision, and frequently the lesion that develops is advanced at the time it is first noted. We have seen a moderately advanced lesion appear within a period of 11 days after a negative chest x-ray film.

In our services an effort has been made to develop greater responsibility on the part of the individual patient. This is done by encouraging the physician to spend more time with the patient, instructing him as to his condition, how to take care of it so as to protect himself and others, and as to the need for periodic medical supervision. The importance of reporting promptly at any time symptoms may appear is stressed. This type of education is reinforced by a nurse's conference with patients for whom further instruction

is needed. The use of an appointment system for patients makes it possible for the doctor and nurse to devote adequate time to this activity. It has been our experience that sufficient intelligent effort devoted to the case at the time a lesion is found, or among those that seem to present a special risk due to close and intimate exposure, will accomplish more in prevention and the detection of early lesions than routine requests for revisits of all members of a household irrespective of their importance. The value of this type of educational approach has been fully justified.

The problem of tuberculosis control is essentially the same everywhere; therefore, the principles of the procedure set forth here should be equally valuable and applicable in the rural or urban clinic. We do not believe these problems or the methods of solution presented are indigenous to New York City.

In the first instance we have applied sound business principles of administration to our service. The objectives of the service must be clearly defined before any constructive procedure can be set up. We have therefore defined our objectives: first, to find tuberculosis, and second, to supervise the case found so that he will not be a source of infection to others and, so far as possible, bring his disease to a stage of arrest. A third objective has been to select from the susceptible population those most likely to develop the disease and supervise them during the period of greatest risk.

Having determined our objectives and procedures, we have taken pains to see that every physician on our staff and every nurse in the department has been fully apprised of the underlying philosophy and the why's and wherefore's of every step. This has been accomplished through group conferences and discussions by small groups of the staff

so that each member has been free to enter the discussion. As a result, the entire staff are working unitedly and intelligently toward a common goal.

The major clinic procedures in the Bureau of Tuberculosis can best be discussed in terms of the answers to the following questions:

1. Whom shall we examine?
2. What shall the examination consist of, and how shall we record it?
3. For how long a period, and how often, shall we supervise patients?

WHOM SHALL WE EXAMINE IN THE CLINIC?

Four types of cases are examined in our clinic services—

1. Cases of tuberculosis
2. Associates of cases of tuberculosis
3. Persons with pulmonary symptoms
4. Persons in susceptible groups on the basis of age, sex, race, or economic status

Cases of pulmonary tuberculosis constitute a small but important part of our clinic case load. Active cases must be given periodic supervision while awaiting hospitalization. Certain individuals with productive or partly fibrotic lesions of doubtful stability are suitable for home care and should be observed at frequent intervals in the clinic. A few active cases in need of institutional care, who refuse to enter a hospital, also require clinic supervision. Most cases of this type should be forcibly detained in the hospital if necessary, and every attempt is made so to handle them in our service.

Most of the cases of pulmonary tuberculosis seen in the clinic are arrested, and have come to us after a period of institutional care, or have reached the arrested stage without treatment, or even knowledge of their disease. These cases require careful supervision until complete stability is assured, particularly during the time when normal activity or productive employment is being resumed.

Associates of cases of tuberculosis

form a large part of the clinic population. These are of two general types, which we designate as possible source cases and contacts.

Possible Source Case: An adult individual in intimate association, in or out of the family, with any of the following types of cases:

- a. Cases of active primary tuberculosis
- b. Closed cases of chronic pulmonary tuberculosis
- c. Cases of tuberculous meningitis
- d. Cases of miliary tuberculosis
- e. Cases of surgical tuberculosis (lymph nodes, bones, skin, abdomen, genitourinary tract, etc.)

Contact: An individual other than a parent, or older relative or associate, who has been in intimate and prolonged or repeated association with an *open case* of chronic pulmonary tuberculosis within the preceding 2 years.

The open case of chronic pulmonary tuberculosis is considered to be one with a positive sputum, or evidence of cavity by x-ray, and therefore presumably infectious. The significance of this distinction will be brought out in connection with the discussion of standards of supervision.

Persons with pulmonary symptoms— The third group of individuals commonly seen in the clinics are those persons seeking examination because of pulmonary symptoms. Many cases of this type are referred by social agencies and welfare organizations, but an increasing number are presenting themselves as a result of the more effective health education of the past few years. Included with this group are those individuals sent to the clinic consultation service by private physicians. The consultation service for private physicians is constantly expanding, and serves a very useful function in making available to the doctor a complete chest examination, including x-ray, by experienced specialists for those patients who would otherwise be unable to

afford such a service. The diagnosis and recommendations for such patients are sent to the referring physician directly.

Persons in susceptible groups—The fourth group, and an increasingly more important one, is composed of persons examined because of the greater likelihood of their developing tuberculosis, and not for any of the reasons cited previously. The increased susceptibility of these individuals is related to their age, racial stock, economic status, character of employment, and similar factors. Our principal approach to this group is through mass x-ray survey examinations, which have been extended to over 600,000 individuals in New York City since 1934.

More recently we have attempted to decentralize much of this work and carry out surveys of selected susceptible groups in the local clinics. While the numbers examined in this manner are smaller per clinic than the mass examinations, they will in the end reach thousands more and utilize to the fullest extent our local x-ray facilities.

WHAT SHALL THE EXAMINATION CONSIST OF AND HOW SHALL WE RECORD IT?

Adequate clinical examination and record keeping are fundamental to any clinic service worthy of the name. This has frequently been taken to mean that a complete history, with detailed information concerning all of the patient's previous illnesses, a general physical examination, tuberculin test, sputum analysis, and radiographic examination must be done on each patient. This we are firmly convinced is neither necessary nor practical. Our main problem is to find tuberculosis. Therefore for the majority of patients a simplified procedure is entirely adequate. We employ the various diagnostic aids according to the following indications:

X-ray examination—All patients receive a posterior-anterior chest roentgenogram at the time of their initial admission to the clinic, and at each periodic supervisory visit. Paper film is used routinely and has proved entirely satisfactory for the initial x-ray and for repeat films on previously negative cases. The cost of 14 x 17" paper x-ray film is a little more than one-third that of corresponding size celluloid films. The latter medium is reserved for rechecking doubtful cases, and in the follow-up of lesions of an unstable character. Special positions are taken only when indicated by the initial film or by fluoroscopy. We feel that the x-ray is the basic method of diagnosis in all cases and has no adequate substitute.

Fluoroscopy—An attempt is made to fluoroscope all new patients and all patients in whom it may provide additional information. We do not substitute it for x-ray, as it does not provide a permanent record and cannot be reviewed.

Tuberculin test—The tuberculin test is used to furnish an index of infection for purposes of supervision and not as a method of selection for x-ray. It is applied to adolescent and young adult contacts who have been removed from the source of infection. Those found negative are not considered contacts and are not followed further. We also use it in infants under 3 years of age on whom it is frequently difficult to secure satisfactory films. Occasionally, the tuberculin test is used as an aid in differential diagnosis. In all the above instances an initial x-ray is taken. Our reasons for not using the tuberculin test as a basis of selection for x-ray are practical and not a lack of confidence in the test. Experience has clearly shown that the application of two tuberculin tests with return on both occasions for reading, followed by x-ray in 20-35 per cent of cases, is not an

economical procedure. Considerable time and effort is spent by doctor and nurse, and both child and parent are frequently disturbed by the repeated use of needles. In many instances the patient fails to complete the tuberculin series or receive the x-ray when the test is positive. The repeated visits required are often a financial burden to the family. All this is obviated by the use of a paper film at small cost, and the detection of non-tuberculous pulmonary conditions is facilitated as well.

Physical examination — It is our opinion that the routine physical examination is not a productive method of diagnosis, and we have eliminated it. Physical examination is employed only when indicated by a history of significant pulmonary symptoms or in cases showing pulmonary lesions by x-ray or fluoroscopy.

History—An elaborate history is not necessary for every patient coming to a tuberculosis clinic. In our service a complete folder type record is made out only for cases with symptoms highly suggestive of pulmonary disease, and for known cases of pulmonary tuberculosis. The records for all other patients are made on 5 by 8" cards. When used for a contact, this card provides complete information concerning the source case and his association with the patient. When used for a case, the card provides a list of common pulmonary symptoms to be checked. Space for x-ray interpretation and notes on revisit is present on the reverse side. This is the only record ever made out for the patient unless a pulmonary lesion is found on the initial or a subsequent film. In such instances the complete folder type record is made out at that time.

Sputum—Sputum examination is performed on all patients with a productive cough, and all specimens are routinely concentrated in our laboratory. The analysis is repeated as often as indi-

cated clinically and is supplemented by gastric analysis and culture when necessary.

Two other short cuts in procedure are employed in our clinics. All x-ray films are interpreted in accordance with a numerical code. This code, which has been published previously,¹ classifies all types of intrathoracic pathology or anatomical variation commonly encountered in a chest roentgenogram by means of a three digit number (e.g., chronic pulmonary tuberculosis, active, minimal—931). The code number does not replace the written description of the x-ray, but does make it unnecessary to rely on a vague or confusing x-ray description. The code is also employed to indicate the diagnosis, and has been adopted in all branches of our service, being used by doctors, nurses, and clerks with facility. The numerical character of the code makes punch card tabulation simple, and detailed analysis can be made through its use that could not be done otherwise.

In an attempt to meet the problem of the increasing demand on our stenographic service, we have introduced a standard form to be used in reporting the results of examination of patients to physicians or agencies. Up to the present such forms have only been used in reporting on cases showing no pathology. This has proved highly successful and we are now planning to employ a mimeographed letter in which the diagnosis and recommendation can be indicated by checking the appropriate box. We recognize that a form letter is not entirely desirable and this is indicated on the letter in the form of a statement explaining the necessity for the use of the form letter because of the present emergency conditions.

FOR HOW LONG A PERIOD, AND HOW
OFTEN SHALL WE SUPERVISE
PATIENTS?

The most important problem facing

any organization engaged in clinic tuberculosis control work is the choice of standards of supervision for patients of various types attending the clinic. There has been a great tendency in the past to avoid meeting this problem through the adoption of a policy best described as "following everybody forever." Such a program is neither sound nor practical. Public health agencies operate on limited budgets and money spent in unproductive activities is always diverted from other more useful fields. Our objective must always be to work in "pay dirt," which means selective clinic supervision and standards based on the relative importance of various groups as sources of case finding. In our service cases are supervised in accordance with the following standards:

Diagnosed cases of tuberculosis—

a. *Active*—An attempt is made immediately to hospitalize all obviously active cases. If this is not possible they are periodically supervised in accordance with their clinical needs. If they are recalcitrant and considered a menace in their households or to the public, steps are taken to detain them forcibly in a hospital.

Cases presenting findings of questionable activity are observed at frequent intervals, monthly if necessary, until a decision as to their status is reached. Their subsequent care will depend on the findings at that time.

b. *Arrested*—Arrested cases are observed at 6 month intervals for 18 months after the diagnosis of arrest is made. If at that time their condition has remained stationary, they are classified as apparently cured and observed as indicated below.

c. *Apparently cured*—Apparently cured cases are observed at yearly intervals. Those lapsing from attendance after 3 years are discharged. There is considerable question in our mind as to the necessity for follow-up of appar-

ently cured cases, and this problem is now being studied.

d. *Pleurisy with effusion (tuberculous)*—If a pleural effusion is present or has been present in the preceding 6 months, such cases are recommended for sanatorium care. Those not institutionalized, or seen for the first time more than 6 months after the acute stage has subsided, are observed at 6 month intervals for a period of 5 years.

Possible source cases—All possible source cases receive an initial examination including chest radiograph. Those found negative are so classified and discharged from further supervision.

Contacts: Contacts are divided into four major groups: Infants (0-3 years of age), children (3-10 years of age), adolescents and young adults (10-25 years of age), adults (30 years of age and over).

a. *Infants*—Infants are tuberculin tested and radiographed on admission. If negative, they are retested every 6 months as long as they remain in contact with the source case. If Mantoux is positive, they are re-x-rayed every 6 months. This procedure is followed until they reach the 3rd year of age. Unless there is evidence of an active tuberculous lesion by the 3rd birthday, all such children are discharged. The parent is instructed to bring the child back if intercurrent respiratory symptoms develop.

b. *Children*—Children examined between 3 and 10 years of age are not tuberculin tested but are routinely x-rayed. If the x-ray shows no evidence of an active tuberculous process the child is discharged.

c. *Adolescents and young adults*—Adolescents and young adults with a history of previous exposure to an open case occurring just prior to, or during adolescence are tuberculin tested. Those failing to react are discharged. If the reaction to the tuberculin test is posi-

tive, or if the contact is still exposed to an open case of tuberculosis, supervision is continued to the age of 25, at 6 month intervals during the first 2 years, and yearly thereafter.

Contacts first seen between the ages of 20 and 25 are followed for 5 years after the last known exposure, at 6 month intervals for 2 years, and yearly for the next 3 years.

Recent evidence would seem to indicate that the maximum period of risk for contacts is during the first 5 years, and particularly during the first 2 years, after the termination of exposure, irrespective of the age of the contact. We are considering confining the supervision of adolescent and young adult contacts to a 5 year period after contact is broken, but examining such patients every 6 months during this period.

d. *Adults*—Our present policy calls for the supervision of adult contacts for a 2 year period after admission to the clinic. They are seen at 6 month intervals during the first year, and again at the end of the 2 year period. If the contact is very intimate supervision may be continued longer.

We have serious doubts as to the significance of exposure in adult life, but recent studies on the frequency of conjugal tuberculosis warrant the adoption of a conservative policy in the handling of adult contacts.

Non-contacts: Persons coming to the clinics for various reasons other than exposure to tuberculosis are routinely x-rayed. If found negative they are discharged.

Filing of records and x-rays—The problem of how to file records and x-rays is one that faces every clinic. The clinician would like to see them preserved indefinitely on all cases. The nurses and clerks working with the records must have them kept so that they can be promptly located, and filed in such a way that counting or analysis

of the file can be readily done. Sooner or later it becomes impossible to meet the wishes of both medical and clerical staff completely. Either the files become so large that too much time is required to locate records, or they become so crowded that they must be cleared for lack of space. It is our feeling that filing can be arranged to serve adequately all the above purposes.

The physician needs the history and x-rays of cases showing pathology for the continued supervision of the patient, or for comparison if the lesion should reactivate at a later date. The negative records are chiefly of interest in the event that the individual returns later with a lesion. The physician is always interested in comparing the films to see if perchance he may have missed the incipient lesion on the first film. Experience has taught us that such comparisons are primarily of academic importance, for, in the final analysis, action must be taken on the basis of the most recent film or physical findings. Consequently we concentrate on preserving records of cases with pathology. Such records are retained in our local clinic stations for 3 years after supervision is discontinued or the patient has lapsed from supervision. The records are then transferred to a central storage unit, abstracted on a 3 x 5" card giving the essential data in regard to diagnosis, sputum, and treatment, indexed and given a number, and the abstract card filed. The x-rays are photographed on 35 mm. microfilm and given the corresponding number and stored in a letter size file. Should the patient subsequently return, the abstract card and an 8 x 10" print of the x-ray made from the microfilm are sent to the local clinic. The photographic copy provides an excellent reproduction of the original film, and the use of 35 mm. microfilm practically eliminates the x-ray storage problem.

For some time the same system was

used for records and x-rays of negative cases not in need of further supervision. We now feel that little is gained by retaining microfilm copies of negative x-ray films, and we have discontinued the practice. An abstract card is made out for such cases, the negative x-ray diagnosis entered on it, and the card filed. The x-ray is then promptly destroyed. Due to the limitations of filing space in our clinics we are now considering abstracting records of cases not in need of supervision immediately on discharge, rather than 3 years later. It is our firm conviction that every clinic, whether large or small, with ample or limited filing space, at some time must clear its case record and x-ray files. If the x-rays to be removed are ever to be referred to again, it is useless to pile them in bundles in a dusty basement or storeroom. Photography on 35 mm. microfilm provides an efficient, relatively inexpensive, permanent method of storage.

Even with rapid clearance of records to central storage, the handling of the records and x-rays remaining in the clinic presents many filing problems. An average sized clinic, seeing 4,000 to 5,000 patients yearly, will accumulate several thousand records within 3 years. If these records are kept in one continuous file, whether indexed alphabetically or numerically, considerable time must be spent in locating, removing and refiling them. The important cases under active supervision will tend to be lost among those no longer attending the clinic, and any counting of the file will be almost impossible. For this reason our case record files are divided. The current file contains the records of cases scheduled to return in 6 months or less. It is small and easily reviewed or counted. The non-current file contains the records of all other cases. Both are arranged alphabetically. A master index or tally file of the names of all patients who have

attended the clinic is kept for ready reference.

X-rays are filed numerically, the patient receiving a new x-ray number each time he is x-rayed. All previous films are brought forward and filed under the most recent number. In this way the films of patients who have not attended the clinic for some time remain in the back of the file, and the current x-rays are all filed together. We start our numbering system over again at number 1 each year to facilitate clearance of the x-ray files on a 3 year basis. We use open steel shelving, extending from floor to ceiling and adjusted to accommodate standard 14 x 17" films in envelopes, for filing x-ray films. The use of a numerical system in which x-rays are constantly brought forward, and open shelves, has made locating, removing and re-filing of films rapid and efficient, and has required a minimum of file space.

Appointment system—An appointment system has been developed in our clinics. It requires some time to accustom the patients to this plan, but in the end it tends to schedule the clinic load at a level that can be reasonably accommodated at each clinic session. This results in more prompt clearance of the individual case, a fact that is deeply appreciated by the patient.

A postal card is sent to all patients, who have been given appointments 6 months or more in advance, a week prior to their due date at the clinic. It is estimated that this reminder is adequate in 50 to 60 per cent to assure the attendance of the case. If the first appointment is not kept, another is made by postal. If there has been no response, the available records are reviewed by the physician. This is where a routine x-ray becomes valuable. The tendency with physicians is to be conservative, and they therefore request return visits for many on general principles; however, if it is found

that coöperation is impossible and the x-ray was negative, many cases can be removed from the file without fear of missing an important case. It must be admitted that 100 per cent coöperation is never possible unless police powers are available.

The *Sanitary Code* of the department makes ample provision for pupils and all personnel in schools and food handlers, as well as others where a serious tuberculosis problem exists. They can be excluded from their work until a satisfactory examination has been made, or in very selected cases they may be forced into a hospital for such examination. This authority is used with great discretion. It is applied to pupils and school personnel, and food handlers refusing to coöperate, almost as a routine; to others on the basis of the seriousness of the problem presented.

SUMMARY

The urgency of the times requires the elimination of every unproductive procedure in the tuberculosis control program if the tuberculosis adminis-

trator and health officer are to meet the increasing demands for clinic service, in the face of decreasing personnel.

The factors under which tuberculosis develops are the same everywhere, and sound procedures that are effective and efficient in one place may be applied in another, be it rural or urban in character.

Tuberculosis administrators must first clearly define their objectives and the procedures necessary for their accomplishment. They must then make certain that all those working with them clearly understand each step in the program. The result will be a coördinated and intelligent approach accomplishing the maximum service with the least expenditure of effort and funds.

These principles have been adopted by the Bureau of Tuberculosis of the Department of Health in New York City with unquestioned success. The major principles involved in our plan have been presented in such a way that it is hoped any clinic handling tuberculosis cases can reap the same benefits in effective and efficient service that we have realized.

Accomplishments in Cereal Fortification*

R. C. SHERWOOD, PH.D.

*Vice-President, Special Commodities Division, General Mills, Inc.,
Minneapolis, Minn.*

PROBABLY no other food and nutrition program has advanced so rapidly as the national movement to fortify cereal foods with vitamins and minerals. Such progress would not have been made without the coöperative efforts of industry, public health workers, and government officials, prefaced by extensive research.

BACKGROUND OF THE FORTIFICATION PROGRAM

The background of enrichment of cereal foods, and the chain of events leading to the establishment of a standard for enriched flour by the Federal Security Agency may be reviewed in the literature.^{1, 2, 3, 4, 5, 6} Cereals, including wheat, corn, oats, rye, and rice, are food items of great importance in the American dietary. Before many of the vitamins had been discovered, animal feeding tests as early as 1919⁷ showed the differences in nutritive value of various portions of the wheat kernel, which we now know were due largely to variations in water-soluble vitamins.

We now have simpler and more direct methods, chemical, microbiological, and fluorometric, for measuring many of the vitamins, which are more rapid and accurate than the time-consuming animal bioassays, and have contributed in

no small measure to the rate of progress in vitamin researches. In fact, without the development of rapid quantitative methods, the determination of the vitamin content of natural foods such as whole grains, and the control of the vitamin content of manufactured foods would not have been possible. Without the fortunate coincidental synthesis and commercial production of certain vitamins required for cereal fortification, the large scale fortification program now under way in the cereal industry could never have been undertaken.

Enriched flour in its present form has resulted from a combination of factors. For more than a generation it has been recognized that whole wheat flour contains growth-promoting factors not present in the same concentration in white or patent flour. With this in mind, whole wheat flour has been advocated for its nutritive value. In spite of many efforts to popularize whole wheat bread because of its vitamin and mineral content or its roughage, it has not met with great favor. For many years the sale of whole wheat flour has represented only 2 or 3 per cent of the total flour sales in the United States.

Some years ago, suggestions of nutritionists and consumer interest in vitamins prompted some millers and bakers to produce specialty flours and breads with enhanced vitamin value to supplement or replace whole wheat bread. The specialty flours have contained

* Presented before the Food and Nutrition Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

different percentages of the wheat kernel and in many cases have been fortified with vitamin preparations and mineral compounds. While breads made with these specialty flours are regarded favorably by some people, because they have more pronounced wheat flavor and higher vitamin content, nevertheless they continue to remain specialty products, with far less consumer acceptance than white bread.

When pure forms or potent concentrates of certain of the vitamins, particularly thiamine and niacin, became commercially available and prices were lowered, it was then possible to produce white flour reinforced with vitamins and minerals.

SETTING A STANDARD FOR FLOUR

This was the situation when the U. S. Food and Drug Administration announced a public hearing on a new standard for flour. At this hearing in September and November, 1940, representatives of flour milling companies and others requested the privilege of including added vitamins and minerals to improve the nutritive value of wheat flour. Sherwood⁸ proposed a definition for a new vitamin-mineral restored flour, suggesting required ingredients (recal-

culated to mg. per lb.) as follows: thiamine 1.9, riboflavin 0.9, iron 18.0, calcium 180. Nicotinic acid was proposed as optional ingredient, a suitable figure to be set later. The amounts were selected so patent flour could be restored to whole grain level and thus a very substantial nutritional contribution could be made to the American dietary. There was debate regarding ingredients and levels, and eventually a definition and standard of identity for enriched flour was promulgated by the Federal Security Agency.⁹

The present standard for enriched flour, and the proposed standard for enriched bread, are shown in Table 1.

The bread standard has not yet become official, but by gentleman's agreement, enriched bread conforms with the vitamin and mineral specifications here shown. During the bread hearing, July and August, 1941, suggestions were made to raise the thiamine, niacin, and iron levels to the figures shown in the third column of Table 1. If these raises are made in the final standard, a corresponding increase in the vitamin and mineral levels in enriched flour will also be required.

The Examiner who conducted the bread hearing has not yet reported his "findings of fact" and made his recommendations in this matter; therefore the specifications listed in the first two columns of Table 1 are now operative, with the exception of riboflavin, the effective date of which has been postponed until April 20, 1943, because of the scarcity of riboflavin.*

PRACTICAL PROBLEMS IN PRODUCTION OF ENRICHED FLOUR

Comparison of the enriched flour standard with average vitamin and iron

<i>Vitamin and Mineral Specifications for Enriched Flour and Enriched Bread</i>			
<i>Minimum Levels</i>			
<i>Ingredient</i>	<i>Flour Federal Standard</i>	<i>Bread</i>	
		<i>Proposed Federal Standard mg/lb.</i>	<i>Modification Suggested at Bread Hearing mg/lb.</i>
<i>Required:</i>			
Thiamine	1.66	1.0	1.1
Riboflavin *	1.2	0.8	0.8
Niacin	6.0	4.0	10.0
Iron	6.0	4.0	8.0
<i>Optional:</i>			
Calcium	500	333	300
Vitamin D	250 U.S.P.	160 U.S.P.	150 U.S.P.

* Effective date of addition postponed until April 20, 1943.

* AUTHOR'S NOTE: Since this paper was presented, Federal Security Agency again postponed the effective date of riboflavin requirement in flour, and also announced a new hearing to review and modify vitamin and mineral specifications for enriched flour and bread. (See *Federal Register*, Mar. 18, 1943.)

TABLE 2

Comparison of Enriched Flour, Plain Flour and Whole Wheat Flour

	Mg. per lb.		
	Whole Wheat Flour	Plain White Flour	Enriched Flour Minimum Gov't Standard
Thiamine	2.3	0.3	1.66
Riboflavin	0.6	0.15	1.2
Niacin	26.0	3.5	6.0
Iron	20.0	3.0	6.0

values for patent flour and whole wheat is shown in Table 2.

Natural grains vary in content of protein, ash, fat, and carbohydrates, depending upon variety and environment during growth, therefore it is not surprising to find variations in vitamin content. Analyses of many samples of wheat have been made in our laboratories. Using these data and others from published literature, we have calculated that two-thirds of the samples tested range as follows: thiamine 1.9 to 2.8 mg. per lb.; niacin 23.4 to 29.2 mg. per lb.; iron 16.1 to 24.1 mg. per lb.

The vitamins and minerals of wheat are not uniformly distributed throughout the kernel. The outer layers of the kernel and the germ are richer in vitamins and minerals than the inner endosperm. Thiamine is the most unequally distributed. Patent flour, which is comprised almost entirely of endosperm, has about one-seventh the thiamine concentration of whole wheat. Of the total thiamine in the wheat kernel, the endosperm contains about 25 per cent, the germ about 15 per cent, and the outer layers of the kernel about 60 per cent. While these values show how the thiamine exists in the natural grain, they do not give a true picture of the thiamine content of the various products of milling, as the commercial process of milling wheat flour does not permit a sharp separation between the various tissues of the wheat kernel.

The distribution of thiamine in the fractions of wheat milling is shown in Table 3. The distribution of thiamine,

TABLE 3

*Thiamine Content of Wheat and Mill Products **

(Averages of samples from several commercial millings)

	Milling Yield Per cent of Cleaned Wheat (approximate)	Thiamine Content	
		Mg. per lb. Average	Calculated as Per cent of Total Thiamine in Wheat
Patent flour	63.0	0.31	8.0
First clear flour	7.0	1.36	3.9
Second clear flour	4.5	5.61	10.0
Red Dog flour	4.0	13.45	22.0
Germ	0.2	10.40	0.9
Shorts	12.3	7.89	39.6
Bran	9.0	4.25	15.6
Cleaned wheat	100.0	2.28	100.0

* Based on data found in references 10 and 11.

niacin, and riboflavin in products of wheat milling differs widely as shown graphically in Figure 1. As the miller lengthens extraction of flour in the range between 70 and 80 per cent, there will be a sharp increase in thiamine, moderate increase in riboflavin, and relatively little increase in niacin.

Enriched flour can be made in two ways—retention, and supplement. The first is accomplished by modifying the flour milling process to produce a long extraction flour, by selecting and blending various mill streams particularly rich in vitamins and minerals. This type of flour will yield bread intermediate in

FIGURE 1

appearance between white and whole wheat bread. Enriched flour made in this manner is apparently poorly accepted by consumers in the United States. The optional ingredients, if used, must be supplemented. Also riboflavin, when later required, must be supplemented, as the mill streams will not provide enough.

The second method requires addition to white flour of thiamine, niacin, and iron. Riboflavin must be added also after April 20, 1943. The vitamins may be used as pure compounds or as vitamin concentrates. At present thiamine and niacin are available in pure form, and probably this form is used exclusively. There are several forms in which iron may be added; most common are ferrum reductum, iron phytate, and sodium iron pyrophosphate. Incorporation of these substances in white flour to make enriched flour is not difficult, but accurate control of mechanical feeders is necessary, and thorough blending of the vitamins and minerals with the flour to form a homogeneous mixture is imperative. Usually this is accomplished by first making a "master mix" containing the vitamins and minerals and a suitable diluent, so that a fraction of 1 per cent of the mix will contribute to the white flour the right amount of vitamins and minerals to yield enriched flour.

Enriched bread can also be made in two ways. It should be obvious that enriched bread will be obtained when enriched flour is used in any bread dough, whether baked in the home or in a commercial bake-shop. The other method is to add a predetermined amount of a vitamin and mineral supplement when mixing the dough. Two kinds of supplements are in common use in bake-shops: (1) concentrated mixtures of the vitamins and minerals either in bulk or in pressed tablets; (2) enriched yeast to which has been added the necessary vitamins and minerals.

Enriched bread, whole wheat bread, and white bread are compared in Table 4.

TABLE 4
Comparison of White Bread, Whole Wheat Bread and Enriched Bread

	<i>Mg. per lb.</i>		
	<i>Whole Wheat Bread</i>	<i>White Bread</i>	<i>Enriched Bread Proposed Standard</i>
Thiamine	1.34	0.35	1.0
Riboflavin	0.82	0.6	0.8
Niacin	13.0	3.5	4.0
Iron	12.0	2.2	4.0

Above breads made with 6 per cent dry skim milk

Extensive experiments have been made to determine whether baking affects the vitamins. Thiamine is the only heat-labile vitamin in this group. Harrel, et al.,¹² have reported that the average loss of thiamine is 16 per cent under medium baking conditions—30 minutes at 425°.¹³ Somewhat lighter baking causes only 10 per cent loss. Nearly all the loss occurs in the crust. The crumb does not reach the temperature of the oven, barely exceeding the temperature of boiling water. In later experiments¹⁴ the loss of thiamine in yeast-leavened loaves was found to be independent of the source of the vitamin. Both whole wheat bread and enriched bread show the same loss in baking. No loss of riboflavin was found during normal baking. Niacin is also stable under normal baking conditions. Likewise iron retains its nutritive value in bread. Thiamine loss in bread is small compared with cooking of meat, in which losses range from 0 to 57 per cent when meat is cooked in various ways.¹⁵

In 1939 Taylor¹ favored a program of improvement in nutritive value of foods, and said: "We should first seek retention of the native vitamins, then restoration when advantageous, then fortification when warranted, leaving medication to the last, applicable to regions and groups where ingestion of vitamins as food components encounters exceptional difficulties." He also stressed the importance of separating prevention

from treatment of vitamin deficiency diseases. Enrichment of flour and other cereal products as now practised may be classed as restoration of fortification, and is clearly a preventive measure. The amounts of vitamins and minerals are designed for maintenance, not for treatment of diseases, in accordance with his proposal.

Dr. Taylor further stated, correctly, in April, 1939, that protective restoration with synthetic vitamin B-1 was feasible in milled products from the technical standpoint, but at that time was impracticable on grounds of price. What progress has been made since then! Less than two years later enriched flour with added thiamine, niacin, and iron was being manufactured at the rate of about one million barrels per month; millions of pounds of enriched bread were being made each month by bakers and homemakers; and cereal breakfast foods fortified with vitamins and minerals were being produced in excess of five million pounds per month.

In February, 1941, several of the flour milling companies started producing enriched flour and commercial bakers began making enriched bread according to the formulae proposed by the Food Committee of the National Research Council. Enriched family flour (the type retailed by grocers) and enriched bakers' bread have continuously been supplied to the public since that date. In a short time after enriched flour was placed on the market, 25 to 35 per cent of the family flour was enriched. A year later estimates indicated that at least 50 per cent of the family flour was enriched. The curve is still going upward. It is now estimated that 65 per cent of the family flour is enriched. The government is now buying enriched flour for our armed forces.

In order to induce all millers to enrich all of their mill-controlled brands of family flour, a movement was started

a few months ago by the Millers National Federation to secure pledges from milling companies. The pledge list as of September 16, 1942, included 215 mills.¹⁶ These mills produce more than 65 per cent of the family flour sold in the United States. According to the agreement, when the pledges reach 80 per cent the mills will enrich all of their mill-controlled family flours. A large number of the mills, including those that produce the largest volume of family flour, have been making enriched flours since the program started over a year and a half ago. Manufacturers and blenders of self-rising flours are also endeavoring to get all of their group to sign up in a campaign for enrichment. Further, a survey of several hundred private brands of flour, including the chain stores, has shown that a considerable number of the top brands are already enriched, and others soon will be. In addition a large percentage of the owners of private brands are prepared to enrich their secondary brands.

Because commercial bread production is carried on in thousands of shops and no shop distributes nationally, it is not easy to make an accurate determination of the amount of enriched bread being made. Surveys have been made, however, that indicate that between 70 and 80 per cent of the white bread made by commercial bakers is enriched. It varies in different areas, in some localities as high as 90 per cent is enriched; in others, where public demand has not been great, a small fraction of white bread is enriched.

The production of enriched flour by the miller, and enriched bread by the baker, is not obligatory under federal regulations although it has official sanction of the Federal Security Agency. However, two states, South Carolina and Louisiana, have passed laws requiring enrichment of all flour and bread sold within their borders. Elsewhere the miller may make either enriched

flour or plain flour, or both; the baker has the same choice.* If, however, the miller chooses the enriched type, the number, kind, and amounts of enrichment agents must be in accord with the prescription written by the Federal Security Agency, and labelling must comply with the regulations of the Food and Drug Administration. As always in such situations, federal regulations are enforceable whenever interstate shipments are made.

RESTORATION IN CEREAL FOODS

Restored or fortified cereal breakfast foods have a different legal status from enriched flour, with the exception of enriched farina, which has the same vitamin and mineral specifications as enriched flour. Other types of cereal foods may be restored to whole grain levels or fortified at other levels at the discretion of the manufacturer. Restoration of cereal foods has been encouraged by the National Research Council through its Food and Nutrition Board, and by the Council on Foods of the American Medical Association. The Council on Foods has granted its Seal of Acceptance when manufacturers have applied and conformed with the Council's regulations.†

The Food and Nutrition Board of the

* The Food Distribution Administrator ordered that all bakery white bread must be enriched after January 18, 1943, for the period of the war emergency. (See FDO 1.)

† In August, 1939, the Council on Foods of the American Medical Association stated¹⁷:

"If vitamin B-1 is to be added to foods, those foods which naturally furnish this vitamin but have lost it in processing should be the foods selected for its restoration. The addition of vitamin B-1 to milled cereal products thus appears to be justifiable."

Later¹⁸ the Council on Foods said:

"Should the manufacturer desire to improve the nutritive value of his product" (referring to breakfast foods) "the Council believes that it is proper to do this within reason. The Council has accepted breakfast foods that can be considered as general purpose foods when they have been fortified with moderate amounts of salts of calcium, iron, and thiamine. A value now has been adopted for 'maximum restoration of breakfast cereal foods with riboflavin.'"

National Research Council has adopted several resolutions setting up broad basic objectives for food fortification. Included in these resolutions is a recommendation for appropriate enrichment of flour and bread, and of corn meal. The board recommends that every practicable effort be made to retain all natural nutrients, especially thiamine, niacin, and iron, in the processing of cereals; and further states that when loss in processing is unavoidable their restoration to whole grain levels is desirable.

Thus it is seen that the addition of vitamins and minerals to flour and other cereal foods has received the endorsement of nutritionists who have given serious consideration to the nutritional needs of the American public. The cereal industries are coöperating to improve in vitamin content foods which are already well known for their protein and caloric values and for their palatability.

Problems differ in the restoration of various cereal foods. Those made from refined cereal products will be lower than whole grain in thiamine, riboflavin, niacin, and iron, and therefore require supplement of all these factors. Those made from whole grains rarely need fortification with riboflavin, niacin, and iron, but require addition of thiamine if any of this heat-labile vitamin has been destroyed by processing. In such cases thiamine addition is made at the end of the manufacturing process. The natural content of three cereals is recorded in Table 5.

TABLE 5

Natural Vitamin and Mineral Contents of Cereals

Constituent	Average Values—Mg. per lb.		
	Whole Wheat	Whole Corn	Oatmeal
Thiamine	2.3	2.0	3.5
Riboflavin	0.6	0.6	0.6
Niacin	26.0	7.0	7.0
Iron	20.0	12.0	16.0
Calcium	140.0	140.0	200.0
Phosphorus	1,600.0	1,400.0	1,800.0

The fortification of cereal breakfast foods is a common practice now. Many brands, available everywhere, are restored to natural grain levels or supplemented to some extent if vitamins or minerals have been lost in processing. Thiamine, niacin, riboflavin, vitamin D, iron, calcium, and phosphorus are being used as supplements in various cereal products, made with wheat, corn, and oats. It is possible that rice similarly fortified will be produced commercially in the future.

In conclusion I wish to quote from an address by Dr. Robert R. Williams¹⁹ given last winter:

Enriched bread and flour can be brought to everyone in six months if we have the whole-hearted support of every nutritionist, physician and social worker. No one need apologize for advocating something less than perfection. Every good movement has to begin somewhere: let us begin with that feature which promises a major, a universal and a prompt benefit. Success in this will only enhance the power and prestige of the entire nutritional program. Failure in this will embarrass and largely sterilize the rest, for we cannot pretend that these long term objectives are essential for this time of national crisis. If enrichment fails now (and I must remind you that it has not yet succeeded here or elsewhere), it cannot be revived within our lifetime. The industries, once disillusioned, cannot be persuaded to take up the torch again.

In the months since Dr. Williams spoke in this manner there has been substantial increase in the quantity of enriched flour and enriched bread supplied to the American public. His goal, however, has not yet been attained. Greater public demand for enriched flour, enriched bread, and restored cereal foods seems necessary to convince all millers, bakers, and cereal manufac-

turers that all flour, bread, and cereals offered for retail sale should be enriched.

Association of Other Malignant Tumors with Cancer of the Skin

HERBERT L. LOMBARD, M.D., F.A.P.H.A., AND
SHIELDS WARREN, M.D.

*Massachusetts State Department of Public Health, and the Laboratory of
Pathology of the Harvard Cancer Commission, Boston, Mass.*

IN spite of great interest in the immunological aspects of cancer, there are no satisfactory biologic or chemical tests of cancer susceptibility or cancer immunity that may be applied to human beings. For that reason the approach to the problem must be considered from the statistical standpoint. While considerable data have been accumulated in this field, there is need for still further information.

Workers in the field of public health are particularly well situated to obtain these necessary statistical data. At the present time there are some divergent viewpoints as to the rôle of susceptibility and immunity in human cancer. It has been generally accepted by surgeons, radiologists, and others dealing with the care of cancer patients that immunity does not exist, but there is a probability that some individuals are more susceptible to the disease than others. The behavior of recurrences and metastases of malignant tumors in human beings would lead one to feel that there is no specific immunity developed by the existence or eradication of a primary growth. Since we have no way of knowing what portion of the population is susceptible to the initial development of a tumor, it is difficult to obtain valid information as to whether certain individuals are more or less susceptible to the development of tumor than are others.

The observations of Warren and Gates^{1,2} suggest that there exists an individual susceptibility to the development of a second malignant tumor in those persons who have already developed one such tumor. A contrasting hypothesis of great interest has been developed by Peller, namely, that "A cured tumor leaves protection of the body against the development of other malignant neoplasms." He has collected a considerable mass of statistical data to support this hypothesis, but its validity hinges in part on the assumption that a relatively small proportion (one-fifth) of the total population is actually susceptible to the development of malignant tumors, and in part on the assumption that case records of cancer patients in hospitals have complete histories regarding previous cancers. If these assumptions can be thoroughly established, much weight should be given to Peller's suggestion that existence of such protection might make it advisable to induce easily cured cancer to protect against those cancers developing in sites where cure is difficult or even impossible.

Peller³ recently discussed the findings obtained from 5,876 cancer records collected from several different sources. These records were studied for notations of previous cancers. Among these records 40 were found which noted the existence of previous cancers. It was estimated that one-half of these might

have been synchronous. Peller estimated the number of former cancer histories he would expect to find among these 5,876 cancer records, using as a base the age-sex specific death rates for cancer in Vienna in 1933 and 1934.

He based his estimates on three postulates. "First, a cured malignant disease is not followed by an increased resistance of the body against the development of a second primary tumor. Second, of all carriers of a surface malignancy only 66.6 per cent survive; of all women suffering from breast or genital cancer only 20.0 per cent were cured; of all other cancer patients only 2.0 per cent do not succumb to this disease." Third, "under usual circumstances, for more than four-fifths of all persons over 40 years old the cancer risk is practically zero. Under these normal circumstances they are not susceptible."

Since from his calculations he obtained an expected figure of 225.6 cases, which exceeded the observed 40 cases, Peller believed that he had established his hypothesis that "A cured tumor leaves protection of the body against the development of other malignant neoplasms."

An opportunity to check the findings of Warren and Gates by other data derived from Massachusetts has presented itself in the series of cancer cases studied in state-aided cancer clinics of the Commonwealth (Series A). This material is particularly valuable in that the patients have been kept under observation for considerable periods of time and the development of tumors among this carefully followed population has been determined with a high degree of accuracy. Here, then, is an ideal means of checking the frequency of the development of tumor among those individuals who have had a previous cancer, either superficial or internal. Whether, or not patients who have had a skin cancer are actually cured of their cancer of the skin is difficult to say, inasmuch

as the studies on cutaneous cancer^{4,5,6} have shown that these lesions are not nearly so easily cured as is commonly assumed and that recurrence, sometimes early and at times very late, or even metastasis, may occur. While the immediate hazard to life of cutaneous cancer is not great, the morbidity rate is very high.

The Massachusetts Cancer Program has been in operation for slightly over 15 years. The follow-up of the patients seen in the state-aided cancer clinics has been excellent, with a lost case record of about 2 per cent. Series A, Tables 1 and 2, comprise an analysis of 1,990 clinic admissions for cancer between 1927 and 1930. The earlier cases have been followed for 13 years and the later cases for 10 years. In this series of cases, therefore, we have the advantage of long and careful medical observation. In this group of patients 5.9 per cent developed a second cancer. The incidence per person per year of observation was 1,195 per 100,000. An expected number of cases to compare with the 117 observed second malignancies was computed. The incidence rate per person-year was assumed to be the death rate plus the cure rate. The percentage of cures was established to lie between 15 and 22 per cent of all cases, and the deaths between 78 and 85 per cent of all cases. When the maximum and minimum incidence rates were applied to the person-years, the expected number of metachronous cancers lies between 80.4 and 85.6. The difference between the observed 117 and an expected situated between 80 and 86 is significant and would suggest a greater susceptibility to an additional cancer among individuals having had one cancer.

In order to obtain data more nearly comparable to those of Peller, we have chosen two other series of cases (Series B and C, Table 1). Series B comprises those cases over the age of 50 admitted

TABLE 1

* Two of these had a second cancer before they were lost.

to the state cancer clinics in 1939. In this series records were scanned for previous admissions to the clinic for other tumors, and the mathematical computations used by Peller were repeated on these data. In order to provide a check on these cases from the clinics, a group of 200 consecutive cases of cancer admitted to the Palmer Memorial unit of the New England Deaconess Hospital was studied to determine whether the past history referred to previous occurrence of a malignant tumor in a given individual.

It must be kept in mind in evaluating a series such as this that, although the

staff at the hospital has been particularly interested in making adequate records and the histories are as complete as it is possible to make them under practical conditions, not a few cases of cured cancer will be missed. Many elderly patients have faulty memories; others forget that a tumor, to them of minor importance, such as a small skin cancer, may have been destroyed; still others may not have been told by their physicians that they have had a cancer. Consequently, as would be expected, our Series B and C show considerably fewer observed cases than does Series A. Series B and C are not directly com-

parable with Series A, because Series A is an actual study of the subsequent fate of a case which has been treated for a cancer, and Series B and C are retrospective studies, necessarily much less accurate, of patients now presenting themselves with a cancer.

However, since Peller's data were based on a retrospective study, we felt it was only fair to include in our material data comparable with his.

Peller believes that only one-fifth of the population is susceptible to cancer and in calculating his expected rates he has used this fraction of the population rather than the total. This figure seems to be based on little more than speculation, since it is based on death rates with an increment added for cured cases, and since he postulates that all susceptible individuals develop cancer. While this may be true, it is at variance with the generally held belief that absence of exciting cause may prevent the development of cancer in a susceptible individual. Until more information is available, it seems useless to estimate the proportion of susceptible individuals in the population.

Table 1 shows the relationship between observed and expected of the four series. The expected of Series B, 74.33, is based on Vienna rates and the assumption that 20 per cent of the population are susceptible to cancer. If 100 per cent susceptibility is assumed, the expected would be reduced to 14.9 with Vienna rates and 7.2 with Massachusetts rates. If Massachusetts rates are used, and an assumed susceptibility of 40 per cent, the observed and expected of Series B would be practically identical. Thus the difference between observed and expected can be made negligible by altering the percentage of susceptibles.

The expected in Series A does not depend on assuming a susceptible part of the population as has had to be done

in the other three series, since we are dealing with a cancer population. The observed numbers of second cancers significantly differ from the expected, calculated from the death rate plus a cure rate.

Peller concluded that "A cured tumor leaves protection of the body against the development of other malignant neoplasms. This remnant protection, though not unfailing, is strong enough to justify endeavors to change the distribution of cancers by site." This conclusion is not confirmed by our data. A careful follow-up of cancer patients reveals a larger number of second cancers than a retrospective study which seeks evidence of multiple malignancy from preceding history. The expected rates computed by Peller are misleading, inasmuch as Vienna death rates, 1933-1934, were used rather than the experience in this country at the period at which risk was present, and an assumed susceptibility of 20 per cent was postulated.

CONCLUSION

There is a greater susceptibility to cancer in persons having one cancer than in the normal population. Whether this susceptibility is caused by the first cancer or is inherent in the individual is not known. There is no evidence to assume that the presence of a skin cancer inhibits other cancers. If anything, the evidence points to the contrary.

Four Years' Use of the Kahn Presumptive Test as a Screening Agency in the Serology of Syphilis*

E. L. WEBB, AND T. F. SELLERS, M.D., F.A.P.H.A. -

Georgia Department of Public Health Laboratories, Atlanta, Ga.

EFFORTS of the U. S. Public Health Service in recent years toward control and eradication of venereal diseases has resulted in a considerable increase in the number of specimens of blood submitted to laboratories of state health departments for the serologic tests for syphilis. In order to examine expeditiously this continuously increasing volume, it has become necessary for some of these laboratories to seek out and employ a supersensitive test as a screening agency for negative reacting specimens. These specimens represent about 80 per cent of the load even in those

laboratory. We have been employing the Standard Kahn test for several years.

The purpose of this paper is to give the results obtained in a four year use of the Kahn Presumptive test as a screening agency in the serodiagnosis of syphilis in the laboratories of the Georgia Department of Public Health. Although this test was not devised by its author primarily for this purpose, it has proved to be an efficient means of conserving the time of both the technicians and those whose duty it is to cleanse and prepare the glassware for re-use.

TABLE 1
Routine Application of the Presumptive and Standard Kahn Tests, 1938-1941

Laboratory	Specimens	Presumptive Test Per cent		Standard Test Per cent	
		Negative	Positive or Doubtful	Positive or Doubtful	Negative
Central	664,459	72.5	27.5	18.1	9.4

Waycross Branch	101,824	64.3	35.7	21.5	14.2
Total	846,506	70.9	29.1	18.8	10.3

states where the incidence of syphilitic infection is the highest.

Some serologic diagnostic procedures employ serum and antigen in more than one proportion. The selection of the procedure is a matter of choice with the

Table 1 gives the number of specimens examined in our laboratory system during the years 1938-1941 inclusive, with the results obtained by the Presumptive and Standard Kahn tests. It is to be noted that of 846,506 specimens examined by the three laboratories, 70.9 per cent were reported negative by the application of an easily performed one tube procedure. It is be-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

TABLE 2

Specimens Giving Negative Reactions by the Presumptive and Positive or Doubtful Reactions by the Standard Kahn Test, 1938-1941

Laboratory	Presumptive Test Negative	Standard Test	
		Negative	Positive or Doubtful
Central	15,688	15,677	11
Waycross Branch	1,798	1,797	1
Total	17,486	17,474	12

lieved that the larger proportion of the survey type of specimen examined in the Central laboratory, and the differences in the incidence of syphilitic infection in the areas served, are responsible for the percentage variation reported negative by the Presumptive test in the three laboratories.

The percentage of positive reactions reported by the Standard test in these laboratories month after month stands in this same seemingly fixed order as presented in this table.

A variation bearing on the practical application of the screen test in different laboratories is shown in the percentage of specimens failing to confirm by the diagnostic procedure. The two branch laboratories, especially the Albany laboratory, serve sections where malaria is much more prevalent than elsewhere. In our studies¹ on non-syphilitic patients infected with malaria, it was observed that the Presumptive more frequently gave positive reactions than the Standard Kahn test.

A large percentage of specimens examined at the Waycross laboratory come from counties where the U. S. Public Health Service has conducted for the past several years a traveling clinic administering treatment to a large portion of the colored population. It is readily conceived that specimens from these intensively treated cases may more often than usual yield positive reactions by the Presumptive, and negative reactions by the Standard test.

For the purpose of developing speed in performance, trainees in the Central laboratory, after acquiring the necessary skill, perform the Standard test on some of the sera found negative by the Presumptive test. If they find a positive reaction on any of these sera, then both tests are repeated by a more experienced technician for confirmation.

The Waycross laboratory was requested by the U. S. Public Health Service to perform for a period of time both tests on all specimens submitted from counties in which an intensive case finding and treatment program was being instituted.

It will be observed, in Table 2, that of the 17,486 specimens examined by both tests, only 12, or 0.07 per cent, gave positive or doubtful reactions by the Standard test, and negative reactions by the Presumptive test. Nine of these 12 specimens gave definitely atypical positive reactions by the Standard test, which is to be expected. Three of them gave typical minor reactions which cannot be explained, unless occasioned by a rare low titer zone phenomenon. One of the atypically reacting sera had to be diluted 8 times before a positive reaction was obtained by the Presumptive test.

Usually the atypically reacting sera will give sufficient reaction in the Presumptive test to be detected, thus enabling one to withdraw the specimen for examination by the Standard test. The number of specimens which would yield positive or doubtful reactions by

the Standard test, if applied, but which escape detection by the Presumptive test, is negligible.

The question might well arise as to the quality of work done in these laboratories. Table 3 presents the composite

intra-state evaluation studies in this same 4 year period. It will be observed that the sensitivity ratings of the Presumptive Kahn test in the three laboratories are in very close agreement. The specificity ratings are in conformity to

TABLE 3

Average Ratings of Sensitivity and Specificity in National Serology Evaluation Studies, 1938-1941

Laboratory	Presumptive Kahn Test		Standard Kahn Test	
	Sensitivity	Specificity	Sensitivity	Specificity
Control Laboratory	83.9	99.9	74.5	100.0
Central Laboratory	83.8	98.5	76.4	100.0

comparative ratings of the Control laboratory and the Central laboratory in the National Syphilis Serology evaluation studies during the period of time covered in this study. It is observed that the spread in sensitivity between the Presumptive and Standard tests is 9.4 per cent in the Control laboratory and 7.4 per cent in our Central laboratory. A greater spread, of 10.3 per cent, in

the screening efficiency portrayed in Table 1, although these specimens were collected in an area served routinely by the Central laboratory. The ratings for the Standard test lie well within the limit for acceptable performance. It is to be noted that all specimens in Tables 3 and 4 giving nonspecific reactions by the Presumptive test gave negative reactions by the Standard test.

TABLE 4

Average Ratings of Sensitivity and Specificity in Intra-State Evaluation Studies, 1938-1941

Laboratory	Presumptive Kahn Test		Standard Kahn Test	
	Sensitivity	Specificity	Sensitivity	Specificity
Central	91.4	99.5	84.9	100.0
Albany Branch	91.6	98.1	81.3	100.0
Waycross Branch	91.2	97.1	84.5	100.0

the sensitivity of these two tests, as revealed in Table 1, is to be expected.

General biologic and pathologic conditions, which may give positive reactions in the Presumptive test, are more frequently encountered in the rank and file of specimens received by public health laboratories than in those specimens originating solely from syphilitic clinics.

Table 4 gives the average ratings of sensitivity and specificity of the Presumptive and Standard Kahn tests in

SUMMARY AND CONCLUSIONS

The Kahn Presumptive test has been utilized for 4 years as a screening agency and has proved to be an efficient test for this purpose. The Standard Kahn test is employed as the serodiagnostic procedure.

Tables are presented giving the results obtained on 846,506 specimens, showing that 70.9 per cent were reported negative by the application of an easily performed one tube procedure.

Sensitivity and specificity ratings on

both tests in national and intra-state evaluation studies are given.

Less than 0.1 per cent of 17,486 specimens examined by both tests gave negative reactions by the Presumptive test and positive or doubtful reactions by the Standard test.

The chief value in the employment of the Kahn Presumptive test as a screening agency lies in the conservation of time and work. For example, the application of the Standard Kahn test to 1,000 specimens would require servicing and reading 3,000 tubes by the technicians, and cleansing by the dieners, whereas, by using the described setup, this number has been cut to less than

2,000 tubes. Likewise, reagents are conserved.

The employment of a supersensitive test as a screening agency would be even more practical in laboratories where the percentage of positive reactions with recognized diagnostic procedures is comparatively low. It would, at the same time, provide a desirable means of daily checking one procedure against another in a sufficiently large number of specimens.

Postgraduate Education of Physicians for Industrial Health Service*

CARL M. PETERSON, M.D., F.A.P.H.A.

*Secretary, Council on Industrial Health, American Medical Association,
Chicago, Ill.*

MUCH of our present-day thinking about educating physicians for industrial health service must perforce be related to the urgent conditions associated with the war. In this connection, the Directing Board of the Procurement and Assignment Service for Physicians has approved two very significant recommendations of its advisory Committee on Industrial Health and Medicine. The first of these defines the essential industrial physician, and attempts to stabilize the existing supply of qualified industrial physicians. The second recommends among other things the creation by the Council on Industrial Health of the American Medical Association of training centers for industrial medical volunteers, using the combined resources of medical schools, bureaus of industrial hygiene, and industrial medical departments.

Under this plan private industry engaged in war production will be notified by all available means that, if they are unable to satisfy a need for the services of a physician locally, they should communicate their requirements to the state chairman of Procurement and Assignment. The request will be reviewed jointly with the Chairman of the Committee on Industrial Health in the State Medical Association and the Director of

the State Industrial Hygiene Service to determine:

1. The industry's need for a physician
2. The nearest available competent replacement

If no competent replacement is available it is contemplated in this program that centers for rapid intensive indoctrination will be provided for eligible physicians. Since Procurement and Assignment agencies, both national and state, are prepared to coöperate, two steps must be taken promptly:

1. Instruction of the committees on industrial health in the state medical associations about the functions they will be called upon to assume under this program.
2. Set about developing centers for intensive training.

FUNCTIONS OF THE COUNCIL ON INDUSTRIAL HEALTH

The Council on Industrial Health has been requested to promote the establishment of training centers, using the facilities of medical schools, bureaus of industrial hygiene, and industrial medical departments.

To meet the peculiar requirements of the present situation, considerable flexibility in the organization of the teaching program is desirable.

1. To permit small groups to be trained at a time, or perhaps even single individuals.
2. To permit entrance into training at almost any time.

The type of organization suggested

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

by Professor Wampler at the Medical College of Virginia most nearly fits these requirements. At that school co-operation has already been arranged with the Bureau of Industrial Hygiene of the State Health Department, the Industrial Commission of Virginia, the State Department of Education, and the medical departments of industries in and near Richmond, to provide practical instruction in industrial health administration, industrial hygiene and toxicology, and industrial medicine and surgery. The latter segment of training will be supplied by individual case study in the University Hospital and out-patient clinics.

Although there are no very sound figures on which to base an estimate, it would seem that individual scholarships of \$250 to \$300 for 3 weeks of training, available to 250 eligible physicians, would amply meet the intensified requirements of war production industry at the present moment.

CONTINUATION STUDY

Meanwhile, plans are going forward to intensify instruction of the introductory or refresher type which will serve to acquaint the profession at large with the essentials of industrial health service. Under this heading we need to consider the requirements of two major groups:

1. Doctors in general practice who must be depended upon to supply improved service if there ever is to be substantial extension of preventive medicine into industry. The details of instruction are reasonably clear—they are to be found in the outline for the "Teaching of Industrial Health"¹—with such modifications as experience and local situations dictate. It is essential, particularly at this time, to bring the instruction to the doctor where he lives and to adjust it to the industrial health problems of his own locality. His time and efforts are too precious at the moment to expend on fruitless study or investigation.

The other group in community service is:

2. The men in specialty practice—the dermatologists, traumatic surgeons, oculists, radiologists, etc., all of whom increasingly are being called upon to apply their special knowledge and equipment to health problems in industry. To facilitate and improve their acquaintance with the relationship between health and work, committees are being set up in each of the special sections of the Scientific Assembly of the American Medical Association, and these committees in turn are urged to establish working agreements with similar committees in the independent specialty societies. In the list of recommendations filed with these committees, education in industrial affairs as a component of training for certification is incorporated. In addition, they are expected to act as clearinghouses of special information for all classifications of physicians.

EXTENDED STUDY

If again we take the long view of our educational problems as opposed to emergency requirements, it seems beyond argument that, if industrial practice is to take on the full attributes of a specialty in itself, we must lay plans for extended graduate study.

My own impression of a fellowship is an appointment in a university or a foundation, of relatively long but undefined tenure, which carries with it certain obligations in respect to teaching and investigation and which is likely to have a restricted rather than broad interest in the field of medical practice. Certainly such appointments are desirable in every sense, but if our definition is correct, fellowships should be associated with or arise out of separately organized industrial health teaching divisions in properly equipped and located medical, public health, or postgraduate schools. We need to capture the interest of influential people in this direction, since I believe that organization of this character would have the effect of vitalizing the whole medical educational approach to industrial health, all the way up from the undergraduate level. With good support it could be done.

However, it has occurred to us that

we should take a leaf out of the book of experience developed by the certifying boards in other clinical specialties by establishing a system of residency appointments as a means of producing a pool of qualified physicians trained in all aspects of industrial practice and with reasonable speed. Appointments would be based on—

A. Proper preliminary qualifications

1. Graduation from a Class A medical school
2. Approved internship
3. Preferably preliminary general or military practice

For residents, then I can visualize some such service as this:

- A. Six months' training in industrial hygiene and toxicology in a university or public health laboratory of industrial hygiene.
- B. Six months' service in the wards and outpatient departments of an approved hospital able to provide suitable clinical material.
- C. Six to 12 months' service in an approved industrial medical department.

With such a background a candidate ought to be able to present himself before a certifying board with excellent prospects for qualifying and, more important, he should be able to undertake the organization and administration of an industrial medical service to the credit of himself and the profession at large.

HEALTH OFFICERS

The problem of training industrial hygienists of the medical variety, or at least of establishing desirable qualifications, has been considered by the Committee on Professional Education of the American Public Health Association. However, we are greatly interested in the professional equipment possessed by local health officers concerning details of industrial health administration. The Council on Industrial Health has established committees in all but a very few of the state medical associations and is now actively pushing similar committee

organization in all important industrial counties. You will not be interested in too much detail, but our recommendations in respect to the specific industrial health activities of such county committees are briefly as follows:

1. The organization of the committee—The personnel of the committee should contain representation from private practice, industrial practice, and the established public health services. These are the three main professional channels through which service is supplied to industry. Each has much to contribute, and none can perform the entire job alone.
2. Objectives of the committee—The committee should understand the components of adequate industrial health service and be prepared to adjust them to existing local medical and public health facilities and to patterns of community medical practice. In this connection, under ideal circumstances, each war production plant regardless of size should have access to:
 - a. A physician who takes genuine interest in a properly conducted industrial medical department and who is willing to devote regular time to service inside the plant. He may function as an individual in one or more plants, or as a member of a group, or as a member in a panel conducted under the auspices of a state or county medical society.
 - b. Good industrial nursing. Industrial nurses with proper preparation, acting under the physician's immediate supervision or standing orders, will constitute the principal source of sustained industrial health activity for most small industrial concerns.
 - c. Industrial hygiene service directed at improvement of working environment and control of unhealthful exposure provided by physicians and others under the guidance and assistance of the specialized personnel in the state or local bureaus of industrial hygiene.
 - d. A plant health program which will include:
 - (1) Good first aid, emergency, and subsequent medical and surgical care for all industrially induced injuries.
 - (2) Proper health supervision through physical examinations and health education.
 - (3) Good correlation with family physician and other community health

agencies for adequate management of non-occupational sickness and injury.

- (4) Good records of all causes of absence from work as a guide to necessary control, and the establishment of proper preventive measures.

3. Activities of the committee—The committee will be expected to undertake any assignment or local situation which requires the exercise of medical initiative and leadership. It is easy to foresee the many problems which will need to be investigated, the many agencies whose interests and activities will need to be correlated, and the many opportunities for education both to professional and nonprofessional groups which will fall to the lot of this committee. Specific instructions will need to be sent from time to time, and the machinery is already available through bulletins, medical journals, direct correspondence, and field work, to stimulate and maintain interest and to provide reasonably uniform methods of approach to specific problems.

Now it is clear that in this kind of organization the local officer will perform a most useful and important function. In fact, it is not out of reason to suspect that success or failure will depend in a very substantial way on the local health officer's grasp of the issues

and his ability to provide continuity of effort and sustained interest. Very likely these local health officials can benefit by the same kind of postgraduate training as we hope to provide the profession at large. However, advice is and will be sought from the American Public Health Association and elsewhere about the steps which will be necessary to bring local health departments into the industrial hygiene picture to a greater extent than has been the case in the past.

SUMMARY

These are some of the recent developments in the general direction of better preparation for all physicians in industrial health. At no time has the whole subject been of greater importance. I believe that we can and should capitalize upon the present widespread interest to lay sound plans for the future.

Undergraduate Training of Industrial Hygiene Personnel*

MILTON H. KRONENBERG, M.D., F.A.P.H.A.

*Chief, Division of Industrial Hygiene, Illinois State Department of Public Health,
and Assistant Professor, Industrial Hygiene, University of Illinois,
College of Medicine, Chicago, Ill.*

THE question of adequately training the undergraduate in diagnosis, treatment, prognosis, and control of industrial illnesses through the teaching of industrial health in medical schools as part of the general curriculum has been discussed from time to time. Now we hear that no changes are to be made in the curricula of medical schools as now established.

What will be the result? The quite general lack of knowledge among physicians at large of industrial intoxications and other physiological upsets from conditions or manner of work, and their frequent failure to associate the occupation or the environment of the patient with the disease for which he is seeking advice and treatment, has been a matter of frequent remark.

In speaking on the question of better preparation of medical students, a former U. S. Commissioner of Labor Statistics some years ago said: "I have never in my life had a doctor ask me what I did, what my job was; it may be that some doctors do ask a patient about his work, but the whole question of occupation as an element of disease or ill-being seems to be ignored except by plant physicians or industrial physicians, and I wonder if they reach

one-half of one per cent of the people who are really working on these poisons."

Medical schools today are charged by law, public opinion, and accepted usage with the responsibility of training a sufficient number of students for recognized changes in the profession. In order, therefore, that the product of medical education may be better able to cope with the demands made by present-day changes, of which industrial health at the moment is representative, medical schools should adjust their curricula to supply this demand without impairing those elements which the experience of the past has proved to be fundamental.

When we consider the widespread interest, publicized events, and group activity during recent years in connection with industrial health, together with the vast amount of literature on the subject, it is surprising that courses in industrial health have not been organized and developed on a larger scale by medical schools. While the field of industrial medicine is perhaps too far reaching to be covered fully in the undergraduate years, the curriculum can be adjusted and a certain number of hours devoted to this subject so that the student will have heard of more than lead, mercury, and phosphorous poisoning as described in the orthodox textbooks on medicine.

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 28, 1942.

The contentions that a crowded curriculum must deny the undergraduate an opportunity to have this subject offered to him and that the "newness" of the subject does not yet permit its addition to curricula can be combated by saying that such addition does not mean a revolution in present curricula. However, its continued absence may cause a minor revolution in the thinking of many who are anxious to have it added. In line with this thought, I quote from a statement made by the late Professor Halsted at the end of a long and acrimonious debate over required courses: "The only way to arrange a curriculum is to give the good teachers what they want and take away the hours from the poor ones."

We stand now indeed at a time of great anxiety and difficulty in the affairs of industrial medical education. Industrial health problems have assumed major proportions, owing to the rapidly increasing industrial population and by the impact of war production. These developments are of vital significance to medical education. While it is not necessary to predict the exact form which medical care of the future will assume, even though the general features are indicated, it is important that every medical student be prepared for adjustments in the relationships of the doctor to the changing professional, economic, and social conditions.

Obviously, conditions within and surrounding medical schools vary greatly, and no one system or plan can be applied uniformly. However, consideration should be given to procedures and methods of instruction which will afford the student an experience as nearly comparable to the other well organized courses in the curriculum as possible. Medical schools must accord industrial hygiene greater distinction.

Only a very few medical schools have made this type of instruction available. Industrial hygiene is widely taught as

a relatively minor function of preventive medicine and public health. Problems in industrial medicine are presented without any relation to prevention and control of exposures and only when examples happen to present themselves in clinics or wards. Industrial medical administration has been almost completely ignored. Yet the experience of a number of medical schools amply demonstrates that reasonable acquaintance with the whole subject can be provided at modest expense through judicious use of time and readily available teaching and clinical material.

In 1928, the principal medical schools and colleges were circularized, calling attention to the situation in regard to industrial health and requesting that at least a minimum of class work along this line be included in their courses. Letters were sent to 72 colleges, and they were requested to reply as to what action would likely result from this communication. Replies were received from 44 schools. Of these, 4 stated that they now have a course in industrial hygiene; in 8 the subject was merely included in history taking of patients; 4 said they would consider the matter; 5 definitely stated they would enlarge their work along this line. A number stated that while there was no specific course given, the subject was included in lecture courses, examination of patients, visits to industrial plants, etc. Seventeen schools requested suggestions as to ways in which the subject could be introduced to their students.

In 1940, the Council on Industrial Health of the American Medical Association published statistics along similar lines. Of the 52 medical schools who reported, the average time allotted to industrial hygiene was about 5 hours. The time allotted in 24 schools was 3 hours or less; in only 7 were 10 hours or more scheduled. Twelve schools offered elective courses. Yet it is interesting to note that 60 per cent

of recent graduates encounter industrial medical problems early in their private practice.

A year later (1941), Dr. Wampler of the Medical College of Virginia reported on the results of a questionnaire he mailed to 76 medical schools in the United States and Canada. All but 2 of the schools replied. The average time allotted was 6.7 hours per school. Fifty-one schools reported a varying number of hours ranging from 2 to 30. Twenty-eight of the 51 schools took their students on one or more field trips. Twenty of the schools reported an increase in the hours given to the subject in the last 3 years, and one reported a decrease. Thirty-five of the 51 schools teaching industrial health offer it through their departments of preventive medicine and public health. One school had a department of industrial hygiene in charge of the teaching, and 1 school had a division of industrial hygiene within the department of medicine that gave the course. Eight of the schools reported a clinic in industrial hygiene which the students attend sometime during their stay in school.

It does seem from these survey reports that there has been some advance in interest and some increase in the average number of hours assigned. However, the impression is that the medical schools have not led the way and have taken only a small part in the progress that industrial hygiene has made. If what I have just covered receives no attention, I fear that in future years medical schools may perhaps richly merit the reproaches of their graduates for failing to recognize the signs of the times.

The student actually comes in contact with industrial health problems in every department of the medical school. He encounters it first in pathology, as well as in physiology. Pharmacology and toxicology offer other sources. When he enters the

clinical years, he progresses through the major departments of medicine and surgery, in each of which he is faced with the differential diagnosis of numerous subjective and objective signs and symptoms having in many instances the industrial environment as a background. In all of these departments, and perhaps quite properly so, emphasis is laid on clinical differential diagnosis. However, the order of approach is such that the student obtains a distorted idea of industrial illnesses as an entity.

What then can be offered as a possible working solution to this problem?

The all-important requirement for improved instruction is a unified plan which assigns over-all responsibility for coordinated classroom discussion, field studies, laboratory and section work to one single teaching division, preferably preventive medicine and public health. While there might be a need for considerable dependence on clinical teaching in the medical and surgical aspects of industrial practice, the testimony of recent graduates clearly indicates that the older methods of divided and unrelated instruction fail to provide dependable and reasonably complete information.

As a matter of fact, progress would be greatly accelerated if many more medical schools, especially those in industrial areas, could develop or attract support for the organization of separate teaching divisions in industrial health, each with its own faculty, affiliations for clinical and demonstration material and facilities for laboratory and field investigation and consultation. Under such an arrangement, there would be greatly improved prospects for the attraction of special teaching talent and material, and support for research into a thousand aspects of industrial health crying for investigation.

In planning for instruction in the undergraduate curriculum, we should

keep in mind the following essential requirements:

Undergraduate teaching

1. Required Courses—These courses should provide lectures, laboratory experience, industrial history taking, and record keeping, section work in wards and clinics, and field trips.

2. Elective Courses—Electives should provide opportunity for more detailed and specific study, personal participation in special projects, individual patient study or personal experience in plant or laboratory.

To make this possible, the curriculum makers should interest full-time and part-time industrial physicians in participating regularly in the conduct of these courses. There are many medical schools that already have on their faculty physicians who are in charge of medical departments in industry. Other industrial physicians could be selected according to university standards and offered faculty ratings. This would encourage and permit them to assume leadership in helping to coördinate the isolated and spotty efforts in this field. These physicians might also demonstrate their cases and thereby provide for a general clinical education of the students. The undergraduate will greatly benefit by being able to observe the early physical impairments of industrial exposures and environments. This is being done in a few instances.

What about the course content? Since the course cannot be haphazard, there must be a program outlined in advance. The lectures should include well chosen subjects. It is not necessary to go into detail here as to subject matter. An excellent outline has already been prepared and published through the joint efforts of the Council on Industrial Health of the American Medical Association and the American Association of Industrial Physicians and Surgeons, Committee on Medical Education. Another excellent guide is one compiled by Dr. Robert Legge of the University of California, Berkeley.

The lectures should not be given by one individual, since this course can be made more attractive by group effort. It has been found beneficial to include in our roster of lecturers an industrial hygiene engineer, a chemist, a nurse, a personnel director, and a workmen's compensation expert. These are readily available in industrial areas.

Since it is not proposed that medical students should be made specialists in industrial hygiene, the school that I represent has designated in its required course a minimum of 16 hours, which are scheduled during the second semester of the junior year. Unfortunately, because of the large student enrollment, field trips are not possible.

In some cases the senior year has been selected as the opportune period to offer such training. However, based on 7 years' experience in teaching this subject, it is my opinion that the medical undergraduate is at his peak of enthusiasm in the latter half of his junior year, which accounts for his regular attendance and his keen interest. In the senior year, I have observed that most students are more interested in and occupied with their internship appointments and, in addition, more apt to favor the clinicopathologic courses off the campus, rather than this so-called "new subject" in the classroom.

The elective course of 32 hours is best offered in the senior year. The registration should be limited so as to attract those students who have shown a particular interest during their junior year enrollment. This will eliminate those who merely take the course for credit. The elective course affords an opportunity to offer advanced didactic work, seminars, laboratory demonstrations, field trips, and clinical material. A short thesis on some special subject should be required of each student at the end of the term.

The clinical clerkship, in inter-departmental and inter-dispensary

schedules, which has been developed as a part of undergraduate instruction to provide a practical clinical experience for the student, is analogous, in a sense, to the laboratory work in the basic sciences in the first two medical school years. This requirement can be offered through hospitals, wards, clinics, and out-patient departments associated with the medical school, or in well organized industrial medical departments whose directing officers are faculty members of the university. However, this phase of the training program appears to be unorganized and sporadic, and continues to remain a problem. It needs further study.

Another development in the training program has been the establishment of occupational disease clinics, so organized that they are recognized formally as one of the branches of a dispensary service. However, medico-legal involvements, together with certain laws and regulations varying from state to state, have tended to impede the utilization of this specialized clinic. If such a clinic is to serve the undergraduate, both management and labor must be brought into the picture. They should examine this development critically and sympathetically if a working plan is to be successful. Here it could be hoped to develop and demonstrate for the undergraduate, under the direction of trained and competent instructors, the medical procedures involved in treating or controlling specific occupational diseases.

A student's final opportunity is available during the intern year. Internships should be adjusted to reflect in greater degree the problems of industrial health. A short service in the medical department of some industry would be highly beneficial. This has been made possible for some of our interns through the courtesy of Dr. Will Lyon, Medical Director, International Harvester Company, who is a faculty member of the University of Illinois

College of Medicine. The intern assignment to this plant is for 6 weeks and is closely supervised by the industrial medical department staff. The whole training period is designed to provide maximum educational benefits.

The framework herein presented is as flexible as the staff available, the number of hours allotted, the interrelation with other departments of the school or outside consultants and agencies, and the enthusiasm of the curriculum makers; and on it may be built as many or as few special tricks of pedagogy as the imagination of the total teaching faculty may provide.

The purpose of the course should be to inspire, to stimulate, to challenge the student; to show him what the problems are, the actual work he may have to do. The health problems of workers and their environment must be brought to the classroom.

A vast unexplored territory in preventive medicine awaits those who will give special study to many conditions which are incident to employment, and which are as yet in many instances little, if at all, understood. The overwhelming importance of preventing disease through proper supervision of the industrial environment, and the need for adequate preparation of medical students so that as physicians they may serve as guides and overseers in this work, will, it is hoped, become increasingly apparent to those who prepare the medical curriculum. Fundamentally, the science of medicine is applicable to industry.

Comparative Study of Presumptive and Confirmative Media for Bacteria of the Coliform Group and for Fecal Streptococci*

A. A. HAJNA, M.S., AND C. ALFRED PERRY, D.Sc.

*Associate Bacteriologist, and Chief of the Bureau of Bacteriology,
Maryland State Department of Health, Baltimore, Md.*

IN spite of the enormous amount of work which has been done to develop simple and efficient methods for the isolation of coliform bacteria from water and other materials, there are still loopholes for inefficiency in our standard procedure. The present practice of first increasing the numbers of coliform bacteria in lactose broth at 37° C. and then confirming their presence by inoculating secondary tubes of brilliant green lactose bile broth at the same temperature, is the most practical procedure yet developed. This has been established by McCrady and others, as not only simple but more efficient than the more involved and more costly plate confirmation method. The efficiency and simplicity of this method is indicated by its adoption in the new shellfish procedure. The correlative procedure of confirming the presence of *Escherichia coli* by inoculating secondary tubes of buffered lactose broth, a modified Eijkman medium, from the primary cultures in lactose broth, is also simple and has likewise been demonstrated to be an efficient method for establishing the number of *E. coli* in water and in shellfish.¹

The studies to be reported here were made in an effort to improve still further upon these methods by developing media of greater selectivity for the coliform group and for *E. coli*. The new "EC" medium presented in this paper is the highly buffered lactose broth described by the authors in 1938,² modified by the addition of 0.15 per cent of Difco Bacto bile salts No. 3 and the substitution of Bacto tryptose for Bacto peptone. The virtue of the bile salts mixture lies in its enhancement of the growth of coliform bacteria,³ and its ability to inhibit more or less completely the growth of fecal streptococci and spore-formers. Studies have also been made on the comparative value of confirmation by a secondary fermentation test in brilliant green bile and by the usual E.M.B. (eosin-methylene-blue) plate method.

In addition, studies are reported on the use of a new medium for the isolation of fecal streptococci. There is, apparently, increasing interest in the use of streptococci as an index of fecal pollution in swimming pools. We have examined samples of swimming pool water for several years for three indices of pollution, namely, for bacteria of the coliform group, for *E. coli*, and for fecal streptococci. Streptococci appear to be more resistant to chlorination than coli-

* Presented before the Laboratory Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

form bacteria and their absence, for this reason, affords a somewhat wider margin of safety. However, the method of examining the sediment from fermentation tubes for streptococci is not entirely satisfactory. It is a rather cumbersome procedure, and possibly not as efficient in recovering streptococci as it might be.

THE PLATE VERSUS THE SECONDARY TUBE METHOD OF CONFIRMATION

In the first study, the object was to secure additional information on the relative efficiency of confirmation of coliform bacteria from primary lactose broth gas tubes by streaking E.M.B. plates as contrasted with confirmation by inoculation of secondary tubes of brilliant green lactose bile broth. In agreement with the extensive work on this point by McCrady and others in 1937,⁴ no significant difference was found in efficiency of the two methods. The simple method of confirming in secondary tubes of brilliant green lactose bile broth gave less than 1 per cent fewer "positives" than the far more involved plate confirmation method. Neither of these methods was efficient, however, for the isolation of *E. coli*. The number of isolations of *E. coli* from E.M.B. plates made from the primary lactose broth tubes was only 69 per cent

of the number isolated by confirmation in secondary tubes of specially buffered lactose broth² at 45.5° C., while isolations of *E. coli* from E.M.B. plates streaked from the secondary tubes of brilliant green bile broth were only 77 per cent of the number obtained by confirmation at 45.5° C. (see Table 1).

All primary and secondary fermentation tubes in which gas was produced, were streaked on E.M.B. plates. Confirmations of coliform-like colonies were made in lactose broth at 37° C. Confirmations for *E. coli* were made in Koser's citrate medium and in buffered lactose broth at 45.5° C.

PRIMARY VERSUS SECONDARY USE OF MODIFIED EIJKMAN LACTOSE BROTH FOR ISOLATION OF ESCHERICHIA COLI

A second study was made to secure further evidence of the efficiency of the simple secondary tube confirmation for *E. coli*. This method consisted of transferring a 3 mm. loopful of culture from a primary lactose broth gas tube at 37° C. to a secondary tube of buffered lactose broth at 45.5° C. The efficiency of this method was compared with that of isolation by direct inoculation of the water into primary tubes of buffered lactose broth at 45.5° C. Primary inoculation into modified Eijkman medium

Total tubes confirmed, coliform group	511	506
Total tubes confirmed, <i>Escherichia coli</i>	322	355	415	467
Percentage gas tubes confirmed for <i>Escherichia coli</i>	68.5	76.0	88.6	100*

* Arbitrarily established for comparison

at 45.5° C. yielded over 11 per cent more "positives" for *E. coli* (see Table 2). In previous studies,¹ similar differences had also been established though the percentages varied. The average difference in the various studies was approximately 15 per cent.

Although there was a significantly lower percentage of isolations of *E. coli* by the simpler method of confirmation in secondary tubes of buffered lactose broth at 45.5° C., the simplicity of the method warrants its use for many purposes. It is especially useful when gross coliform as well as *E. coli* determinations must be made, since the same

primary standard lactose broth culture can be used for a secondary tube confirmation of the coliform group bacteria and for a secondary tube confirmation of *E. coli*. As seen from a comparison of Table 1 and Table 2, the difference between the number of confirmations for the coliform group by the plate versus the secondary (brilliant green lactose bile broth) tube method is insignificant, less than 1 per cent.

LAURYL SULFATE TRYPTOSE BROTH VERSUS STANDARD LACTOSE BROTH

A third study was made to secure further evidence of the value of the new

* SLB = Standard lactose broth

† LST = Lauryl sulfate tryptose broth

B.G.L.B. = Brilliant green lactose bile broth

lauryl sulfate tryptose broth of Mallmann and Darby.⁵ The results presented here confirm the claims of the authors. In 1,016 primary fermentation tubes inoculated with various amounts of water from 127 samples, 78 per cent of the lauryl sulfate tryptose gas tubes were confirmed for the coliform group in contrast to only 51.6 per cent of the standard lactose broth gas tubes, a difference of 26.4 per cent. This increase in the number of coliform group isolations resulted in an increase in the number of isolations of *E. coli* when secondary buffered lactose broth confirmation at 45.5° C. was used. There were more than twice the number of false presumptives (gas in 48 hour primary tubes) for the standard lactose broth as for the lauryl sulfate tryptose broth (see Table 3).

A NEW "EC" MEDIUM FOR THE COLIFORM GROUP AT 37° C. AND FOR ESCHERICHIA COLI WHEN USED AT 45.5° C.

Although the inhibitive action of bile salts against Gram-positive bacteria was well known, earlier attempts of the authors to use bile salts to secure a more selective medium for coliform bacteria and especially for *E. coli* had not

been successful. Use of MacConkey's bile salt medium at 45.5° C. was tried, but was not found to be as satisfactory as the authors' special buffered lactose broth⁶ for the isolation of *E. coli*. The use of Bacto bile salts No. 3 in buffered lactose broth both at 37° C. and at 45.5° C. has, however, given excellent results with a limited number of samples. The formula for this medium is as follows:

"EC" MEDIUM

<i>Ingredient</i>	<i>Gm. or ml.</i>
Distilled water	1,000 ml.
Bacto tryptose	20 gm.
NaCl	5 gm.
Lactose	5 gm.
K ₂ HPO ₄	4 gm.
KH ₂ PO ₄	1.5 gm.
Bacto bile salts No. 3	1.5 gm.

Titration of pH and filtration not necessary.
Final pH 6.9. Sterilize in autoclave at 15 lb. pure steam pressure for 15 minutes.

The ability of this medium to inhibit fecal streptococci was strikingly demonstrated when inoculations of mixed cultures of coliform bacteria and fecal streptococci were made. After incubation at either 37° C. or 45.5° C., with the exception of an occasional streptococcus remaining from the original

TABLE 4

Comparison of "EC" Medium with Standard Lactose Broth as a Primary Medium for Isolation of Coliform Bacteria at 37° C. and as a Secondary Confirming Medium for *Escherichia coli* at 45.5° C.

No. Samples	Sample	Primary medium 37° C.	Tubes inoculated	Gas tubes 48 hrs	Secondary Confirmation					
					Coliform group B.G.L.B. 37° C.		Escherichia coli "EC" 45.5° C.		Coliform group false-presumptive	
					No.	%	No.	%	No.	%
64	Tap water, treated	SLB	512	80	6	7.5	0	74	92.5
		"EC"	512	17	17	100.0	1	5.9	0
43	Tap water, untreated	SLB	344	52	27	52.0	14	52.0	25	48.0
		"EC"	344	24	24	100.0	14	58.3	0
40	Raw water, well and spring water	SLB	320	174	94	54.0	69	39.8	80	46.0
		"EC"	320	104	104	100.0	68	65.3	0
147	Summary	SLB	1,176	306	127	41.5	83	27.1	179	58.5
		"EC"	1,176	145	145	100.0	83	57.3	0

"EC" = *Escherichia coli* medium

transfer, only Gram-negative rods could be found.

When 147 samples of water were inoculated, in parallel, into both standard lactose broth and the new "EC" medium, 12.5 per cent more positive coliform isolations were obtained with the latter. The specificity of the new "EC" (*E. coli*) medium in this small series of samples, was 100 per cent. Every primary gas tube was confirmed for coliform bacteria (see Table 4).

It was of interest that the same number of isolations of *E. coli* were obtained from secondary inoculations into the "EC" medium at 45.5° C. regardless of whether the primary inoculation had been made into "EC" medium at 37° C. or into standard lactose broth at 37° C. However, due to the fact that no false coliform presumptives occurred with the new "EC" medium when used at 37° C., the percentage of confirmations for *E. coli* was double that obtained with the standard lactose broth.

COMPARATIVE VALUE OF "EC" AND LAURYL SULFATE TRYPTOSE MEDIA

The question arose as to the comparative values of the "EC" broth and Mallmann's lauryl sulfate tryptose

broth. More extensive work needs to be done in this respect, but a comparative study was made on 33 stool specimens and 25 samples of raw sewage (see Table 5). High selectivity of the "EC" medium for bacteria of the coliform group was observed. Both the lauryl sulfate tryptose medium and the "EC" medium gave excellent results, since practically the same number of coliform organisms was recovered. The specificity of the "EC" medium appeared to be slightly better, since 100 per cent of the sewage gas tubes were confirmed for coliform bacteria by this medium in contrast to 98.7 per cent by the lauryl sulfate tryptose gas tubes. The "EC" medium almost completely inhibited the growth of fecal streptococci as shown by the use of the "SF" medium, which will be described next (see Table 5).

A NEW "SF" MEDIUM FOR STREPTOCOCCUS FAECALIS

The need for a selective medium for fecal streptococci which has certain values as an index of pollution in swimming pools, has been referred to. A new medium known as "SF" (*Streptococcus faecalis*) was devised for this purpose.

TABLE 5

Comparative Value of Standard Lactose Broth, Lauryl Sulfate Broth and "EC" Broth for Recovery of Coliform Bacteria and *Escherichia coli* from Feces and Sewage

	Fecal strep.	<i>Esch.</i> <i>coli</i>	Fecal strep.	<i>Esch.</i> <i>coli</i>	Fecal strep.	<i>Esch.</i> <i>coli</i>
Fecal strep. and <i>Escherichia coli</i>	52	52	0	52	52	0
Fecal strep. only	18	0	0	15	18	0
<i>Escherichia coli</i> only	0	30	0	30	5	0
Negative for both	0(12)	0	0	3	8	0

The medium combines the use of an inhibiting agent, sodium azide, for Gram-negative bacteria with temperature selection at 45.5° C. As a result of the work of Snyder and Lichstein⁷ and Hajna and Perry⁸ a concentration of sodium azide was decided upon that would allow streptococci to grow and yet restrict the growth of Gram-negative bacteria. The ordinary preponderance of Gram-negative over Gram-positive bacteria in fecal specimens cultured in the Eijkman medium is practically reversed by this concentration of sodium azide. The choice of the incubating temperature was decided upon as a result of Sherman's work on the *Enterococcus*⁹ group and by the authors' studies on antagonism between *E. coli* and *S. faecalis*.⁸ This medium has proved highly specific for fecal streptococci. The appearance of growth in the "SF" medium at a temperature of 45.5° C. and an acid reaction, as shown by the brom cresol purple indicator in the medium, are almost complete evidence of the presence of *S. faecalis*. The formula of this new "SF" medium is given here.

Both "EC" and "SF" media have been found highly selective for coliform bacteria and for fecal streptococci, respectively, in milk (see Table 6).

"SF" MEDIUM

Ingredient	Gm. or ml.
Distilled water	1,000 ml.
Bacto tryptone	20 gm.
NaCl	5 gm.
Glucose	5 gm.
K ₂ HPO ₄	4 gm.
KH ₂ PO ₄	1.5 gm.
Sodium azide NaN ₃	0.5 gm.
Brom cresol purple (1.6% alc. sol.) indicator	2 ml.

Sterilize in autoclave at 15 lb. pure steam pressure for 15 minutes.

SUMMARY

1. Confirmation of coliform bacteria by inoculation of secondary tubes of brilliant green lactose bile broth has been found as efficient as the more involved E.M.B. plate method.

2. Confirmation of *Escherichia coli* by inoculation of secondary tubes of buffered lactose broth at 45.5° C. is also a simple practical method. The addition of 0.15 per cent of Bacto bile salts No. 3 to this medium, with a slight modification as to amounts of other ingredients, promises a method of efficiency comparable to the brilliant green lactose bile broth method for the coliform group.

3. Lauryl sulfate tryptose broth has been found to yield many more positives for the coliform group than standard lactose broth and to give comparatively few false presumptive reactions.

4. A new "EC" (*E. coli*) medium has been found equally as efficient for the isolation of coliform bacteria as lauryl sulfate tryptose broth and to give no false presumptives on a

series of 147 samples of treated and untreated waters. This medium inhibits almost completely fecal streptococci and other Gram-positive bacteria with no apparent inhibition of coliform bacteria.

5. The new "EC" medium can be used equally well for the isolation of coliform bacteria at 37° C. or for the isolation of *E. coli* at 45.5° C. It can be used either as a primary medium for the growth of *E. coli* or as a satisfactory secondary medium for the confirmation of *E. coli*.

6. A new "SF" medium is described which is highly specific at 45.5° C. for fecal streptococci. The mere presence of growth and acid in this medium at 45.5° C. is confirmatory evidence of fecal streptococci. The medium may be inoculated directly with water, milk, or sewage, or may be inoculated from other primary media, such as standard lactose broth.

A Practical Housekeeping Program for Industry*

HERBERT G. DYKTOR, F.A.P.H.A.

Chief Engineer, Bureau of Industrial Hygiene, Michigan Department of Health, Lansing, Mich.

IN spite of diligent efforts to find a good definition of the word "housekeeping," I have been unsuccessful. I have also discussed this subject with many people, and most of them gave different interpretations. Possibly there is no exact definition of the word, and, therefore, it may not be presumptuous on my part to say what housekeeping means to me when it is related to an industrial establishment.

Industrial housekeeping means more than the slogan "a place for everything and everything in its place"; it must mean more than painting aisles and sweeping the aisles. To me, it is that indefinable reaction when making an inspection, that here is a plant, well organized, well kept, and on its toes in plant hygiene. For a plant to create this reaction on a trained observer involves a great deal of planned effort and some expenditure by management, and this cannot be accomplished either casually or in a day or two.

Housekeeping is not such a simple matter as it may seem, and so it may not be amiss at this point to review very briefly some of the fundamental considerations underlying good plant housekeeping.

In recent years, the meaning and

scope of housekeeping has expanded until now many understand it to include supervision of sanitary facilities, locker rooms, and the attendant problems of proper water supplies and sewage disposal systems, in addition to the usual cleaning and sweeping operations.

ELEMENTS OF A GOOD PROGRAM

In my opinion, good housekeeping comprises the following elements (these are not necessarily in order of importance):

1. Men and machines should be so placed as to provide the easiest and most efficient flow of production.
2. Operations should be so located that the health hazards, possibly associated with one will not imperil workers on another task.
3. Structural and operational arrangements should be made to permit easy traffic of men and materials within the plant.
4. Adequate space should be allotted for the storage of movable equipment and tools not in current use.
5. A safe water supply and proper sewerage and sewage disposal facilities must be provided.
6. Definite janitor service should be furnished for the regular cleaning of sanitary facilities, locker and eating rooms, windows, lighting fixtures, and other parts of the interior of the plant.
7. Proper maintenance of all equipment must be enforced; this will become a relatively easy matter if the other items are carried out in a conscientious manner.

I shall not bore you with the func-

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 29, 1942.

tional details involved in the foregoing seven elements of good housekeeping. Detailed information has been furnished by several capable authors and is readily available. However, I shall tell you some of the reasons why good housekeeping is so essential to all plants.

REASONS FOR PROGRAM

A plant may or may not handle material hazardous to health. That is beside the point, but every plant should have a health and a safety program. They are basic to all plants, and I do not know of anyone who would not benefit by having them.

It is my contention, however, that you cannot have either a good health program or a good safety program without the foundation of good housekeeping. What would be the use of passing workers through a screen of physical examinations, assigning them to suitable tasks, and then exposing them, for instance, to heavy dust concentrations often due to poor housekeeping, or to the potential danger of infection because of lack of proper sanitation? What would be the use of having a fine safety program on paper if you exposed workers to accidents because of improper stacking of materials, bad floor conditions, or poor equipment maintenance?

To my mind, the logic of having good housekeeping as a basis for any health maintenance or accident prevention program is quite plain. I do not believe that it is necessary for me to convince you on this point. Rather do I believe that it might be well to study the situation and apply remedies where needed.

We know that the annual loss of industrial man-hours due to occupational mishaps is increasing, and we know from observation that at present housekeeping often is neglected, especially in the smaller plants. Probably there is a definite connection between these two

concurrent experiences due, perhaps, to a combination of emphasis on production, overcrowding of manufacturing facilities, inexperienced labor, and lack of proper supervision.

Whatever the reasons for this state of affairs may be, the results speak for themselves and they are not so good. I suggest that a considerable improvement may be attained by initiating and maintaining a thoroughgoing plan of better housekeeping in all plants, particularly in the smaller plants. In the latter, good housekeeping may frequently be the only readily available means of controlling occupational hazards, and for this reason it is doubly important.

The industrial hygienist takes the first step in establishing the kind of housekeeping program I have in mind. He must make a thorough sale to plant management as otherwise his effort will merely produce sporadic attempts and temporary effects. To be successful, the sale must result in a program that is well conceived and practical. It will then be carried out conscientiously as an everyday routine.

No matter how small the plant, a good housekeeping program will cost some money, both for fixtures and for labor. Therefore, the authority for carrying out the program must be delegated by management to some one person. It is my belief, in the light of past experience, that authority cannot be successfully delegated to a committee because of the frequent inability to get unanimous opinions, procrastination on details, and general inertia. We all know how committees proceed unless one man takes upon himself the burden of getting prompt action. And so, why not appoint one man for the job, in the first place?

In the larger plants which employ a full-time safety director or engineer, he is, of course, the indicated person to assume responsibility for proper house-

keeping, but in the smaller plants, not possessing the services of such a man, the selection will depend on certain considerations.

I do not believe that the plant superintendent is the man for the job. As a rule, his efforts are concentrated on production. In addition to this full-time job, he has numerous other responsibilities, all connected with manufacture and labor. Neither is one of the foremen the man for it. Generally speaking, their world is restricted to just a portion of the plant, and, therefore, they may lack the proper perspective, and their prestige with the workers in other departments may not be such as to permit them to enforce regulations.

It seems to me that the employment manager may fill the bill in most cases. Generally he has the responsibility for hiring personnel, exercises related functions such as group insurance, workmen's compensation, and general welfare activities. He is well known to all employees, is respected because, in many instances, he represents management to them. Moreover, his duties place him in close contact with company officials and his requests receive attention and consideration.

If the plant is too small to have an employment manager, then the responsibility for plant housekeeping could very well devolve on one of the company officials, preferably the treasurer since he is the man who handles the purse strings. It will also be an advantage to have such an official take an active interest in the workers' environment and its attendant difficulties and thereby contribute substantially to a better understanding between labor and management.

Individual conditions will govern the selection of the man for taking charge of a plant housekeeping program but its importance compels great care in making that selection.

THE PROGRAM

Once the proper man is selected, he will, in company with the superintendent, make a survey of the plant and find the location of bottlenecks caused, for instance, by an outdated arrangement of machines or by a badly timed system of supply and removal of materials. With the superintendent he will decide on the necessary steps to establish a smooth production flow. He will segregate or isolate operations which may inconvenience, annoy, or endanger neighboring operations. He will observe movement of men and materials throughout the plant and, in coöperation with the various departments, decide on the direction of traffic. To that end, he may decide on the relocation of doors, removal of obstructions, demarcation of old and new aiseways, and structural alterations. He will also observe the disposal of little used equipment and tools and will devise a space where they can be stored systematically and not become junk, if of subsequent real value to the company. He will call for the maintenance man and with him make a thorough trip of the plant and inspect machines, protective equipment and other devices, and demand that they be put in good condition immediately, if necessary, and thereafter be reinspected and rechecked at regular intervals.

Having accomplished the foregoing and acquainted himself with the inner workings of his plant, the selectee will consult his state or local health department on matters pertaining to water supplies and sewage disposal, particularly if the plant is not connected with municipal systems. He will also ascertain from his state health department or labor department what regulations are in force relative to sanitary and kindred facilities, and if women are employed in the plant, what special regulations exist for their benefit.

He will make up a list of daily,

weekly, monthly, and quarterly chores that will have to be performed by the janitor, such as cleaning of the various sanitary facilities, windows, light fixtures, etc. He will go over the list in detail with the janitor and personally investigate and supervise the various items on the list. This list may then well be called the janitor's "standing orders," and will have to be carried out faithfully and consistently.

Finally, the housekeeping supervisor will have to draft a schedule for himself for the regular inspection of the plant in order to make certain that there is no slackening in service and that the plant is maintained in apple-pie order.

All this may sound difficult and tedious but all worth while objectives involve work and expenditure, and plant housekeeping is no exception.

Before closing, I should like to say a few words concerning coöperation of the workers. Experience has shown that without the sincere collaboration of labor, management may not have an easy time with the maintenance of good housekeeping in a plant. Industry as a whole has been convinced for a long time that it is good economics to keep workers at their tasks and reduce absenteeism, from whatever cause, to a vanishing point. However, some of the innovations instituted by manage-

ment have often been misunderstood and therefore are opposed by labor. It may be reasonably expected, therefore, that if before a housekeeping program is put into effect, time is taken to explain the program to the workers, the results might be beneficial to all concerned. While this discussion stresses the importance of good plant housekeeping as a foundation for all other health conservation and safety programs, the conclusion should not be drawn that these programs are not advocated. On the contrary, they should be carried on with unabated vigor, but they will be immeasurably strengthened by a good housekeeping program.

To summarize the proposed program:

1. Management appoints a supervisor, preferably the employment manager, to set up and carry out a housekeeping program.
2. Management gives the supervisor authority to incur expense for fixtures and additional labor.
3. Supervisor consults department heads and labor to improve production flow, plant traffic, and storage of unused equipment.
4. Supervisor ascertains state and local regulations concerning sanitation.
5. Supervisor works out a plan with the maintenance man to keep equipment in good condition.
6. Supervisor provides janitor with itemized orders for regular cleaning of the plant interior.
7. Supervisor establishes a routine for the periodic personal inspection of the plant.

Typhoid Vaccine Studies VII: Typhoid-Paratyphoid Vaccine*

LIEUTENANT COLONEL DON LONGFELLOW, M.C., AND
MAJOR GEORGE F. LUIPPOLD, SN.C.

Typhoid Research Unit, Army Medical School, Washington, D. C.

FOUR previous communications^{1, 2, 3, 4} emanating from the Typhoid Research Unit of the Army Medical School have been concerned with studies of monovalent typhoid vaccine. This paper reports our first investigations since World War I of typhoid-paratyphoid vaccine—often referred to as “triple typhoid” and as “T.A.B.” vaccine.

The bacterial content of the typhoid and typhoid-paratyphoid vaccines prepared at the Army Medical School has been changed from time to time since 1916, to meet existing conditions. In 1934 it was simplified to a monovalent typhoid product. These changes have been reviewed in a previous publication.⁷

In September, 1940, the preparation of triple typhoid vaccine was resumed; and since then, the combined T.A.B. product prepared in the Division of Biologic Products of the Army Medical School has consisted of 1,000 million typhoid bacilli and 250 million each of the paratyphoid A and B components per ml. of material. Aside from its modification in bacterial content from any previously used T.A.B. vaccine, the 1940 product is different in respect to the strains of organisms employed in its preparation. The old “Rawlings” strain of *Eberthella typhosa* has been

replaced by the more immunogenically active Panama “carrier” strain 58 (Army Medical School culture collection No. 42-A-58); and the strains of *Salmonella paratyphi* and *Salmonella schottmuelleri* are also different from those formerly used.

SELECTION OF STRAINS OF PARATYPHOID ORGANISMS

Selections of strains of *S. paratyphi* and *S. schottmuelleri* to be used in the 1940 type of T.A.B. vaccine were based, in general, on the same criteria as was the selection of the strain of *E. typhosa* in 1935.⁵ A number of colonially smooth strains of each species were chosen from the Army Medical School culture collection and from outside sources, and titrated for mouse virulency. The most virulent of each species was selected for observations of cultural characteristics and biochemical behavior. Productivity of agglutinins and of protective substances was next determined; and lastly, the capacity of these organisms (prepared as vaccines) actively to immunize mice against heterologous strains of homologous species was ascertained.

No difficulty was experienced in the selection of a suitable Para B organism. Strain 41-H-6 of the Army Medical School culture collection was highly virulent for mice (m.l.d. 1 to 10 organisms in 5 per cent mucin); it produced a high agglutinin titer in rabbits, and the rabbit antiserum conferred a

* Presented at a Joint Session of the Health Officers, Laboratory, and Epidemiology Sections of the American Public Health Association at the Seventy-first Annual Meeting in St. Louis, Mo., October 27, 1942.

high degree of immunity on mice to an heterologous strain of *S. schottmuelleri*. Culturally and biochemically, strain 41-H-6 was a typical Para B organism, growing luxuriantly on infusion agar and emulsifying readily in physiological saline solution. Prepared as a vaccine, this organism protected mice against several hundred m.l.d.'s of an equally virulent strain of *S. schottmuelleri*.

In the case of the Para A culture, however, the most virulent of the strains titrated (41-N-8, A.M.S.) was found to be relatively avirulent, its m.l.d. in 5 per cent mucin ranging between 1 million and 10 million organisms. Otherwise, except for its comparatively sparse growth on infusion agar, this strain of Para A was fairly satisfactory. It was culturally smooth and biochemically typical of *S. paratyphi*, and it produced a satisfactory agglutinin titer in rabbits; but its productivity of immune substances, as determined by the mouse protection test, was difficult of appraisal because of the enormous numbers of test organisms required to represent multiples of the m.l.d. Prepared as a vaccine, it exhibited a demonstrable protection to mice against other strains of Para A, but here again the higher multiples of the m.l.d. amounted to overwhelming doses of foreign protein against which vaccination could not be expected to protect.

The avirulency of *S. paratyphi* 41-N-8 caused us no little concern; and when we learned from an antigenic analysis made in April, 1941, by Edwards⁶ that this strain, as we were carrying it, was deficient in O-antigen I, we instituted a search for an antigenically complete strain which was more virulent than 41-N-8. This search did not end until one year later.

Antigenically complete strains of Para A, as determined by typing with diagnostic sera, were not difficult to find; but invariably they proved to be no more virulent than, or not as virulent

as, our strain of 41-N-8. We adhered to the belief that virulency was somehow correlated with immunogenicity—but only because vaccines prepared with these avirulent but antigenically complete strains of *S. paratyphi* did not protect mice as effectively as a vaccine prepared with our antigenically deficient, but somewhat more virulent strain 41-N-8.

As a typical example of the results we obtained when making such comparisons of the immunogenicity of strains of *S. paratyphi*, a representative protocol is reproduced (Table 1) from the first announcement of this finding reported by one of us earlier this year.⁷

Referring to Table 1, strain CA is antigenically complete, being strongly agglutinated by I, II, XII, and a diagnostic sera; yet, when prepared as a vaccine, it is relatively inferior to the antigenically deficient strain 41-N-8.

The point of this discussion is that antigenic completeness of an organism, as determined by typing with diagnostic sera, is not synonymous with immunogenic effectiveness, as determined by active immunization of mice with vaccines or by passive immunization of mice with immune sera produced by vaccines. It is desirable, of course, to use a vaccine strain of an organism which is antigenically complete; but the decisive criterion for its acceptance should be the quality of the organism's performance, as a vaccine, in the animal body.

Our search for a replacement for strain 41-N-8 ended in the receipt of strain HA-6 from Dr. A. Felix, of London. This strain (hereafter referred to as 41-N-22) proved to be more virulent than any culture of Para A we had thus far worked with, its m.l.d. for mice ranging between 10,000 and 1 million organisms in 5 per cent mucin, averaging 100,000 organisms. It is culturally smooth and biochemically typical of *S. paratyphi*; upon being typed with diag-

TABLE 1

nostic sera, this culture is antigenically complete; and as a final qualification leading to its adoption, a vaccine prepared with strain 41-N-22 proved to be more immunogenically potent than strain 41-N-8 vaccine. Strain 41-N-8 was thereupon discarded, and strain 41-N-22 has been the paratyphoid A component of our T.A.B. vaccine since March 27, 1942 (T.A.B. Pool No. 119). We are not at all certain that this replacement represents the ultimate in Para A organisms, and we still desire to obtain cultures of this organism from recent isolations for comparative studies.

CIRCULATING PROTECTIVE SUBSTANCES PRODUCED BY T.A.B. VACCINE

As a means of determining the immunologic response of the animal body to vaccination, we know of no method which is more practical and more informative than titration of blood serum for protective substances demonstrable by mouse protection tests.²

A number of these tests were performed with sera of young adult males, initially inoculated with T.A.B. vaccine. These individuals had no history of

previous typhoid vaccination, nor of any recognized enteric infection. Their sera were titrated for protective substances active against (1) alien strains of the typhoid-paratyphoid organisms comprising T.A.B. vaccine, (2) heterologous types of *Salmonella*, and (3) coliform organisms containing *Salmonella* O-antigens.

Individual Typhoid, Paratyphoid A, and Paratyphoid B Protective Titers—

These were determined by routinely performed serum protection tests, and are represented here only in tabulated form. It will be noted that the results of titrations of two groups of individuals have been entered in Tables 2, 3, and 4. Titrations of sera from persons vaccinated with the original 1940 type of T.A.B. vaccine, containing the relatively avirulent strain of *S. paratyphi* 41-N-8, were made soon after this vaccine had been adopted by the Army. Replacement of strain 41-N-8 with the more virulent strain 41-N-22 necessitated a revaluation of the T.A.B. product in respect to the production of protective substances active against alien strains of all three organisms comprising T.A.B. vaccine.

COMMENT: It will be noted (Table 2) that some improvement in the production of typhoid protective titers is evident in the group vaccinated with the present T.A.B. product, over the titers produced by the T.A.B. vaccine containing strain 41-N-8 of *S. paratyphi*. However, to those who have followed this series of studies, it will also be noted that even the titers resulting from inoculation with the present vaccine are

not, in general, as high as those following inoculation with monovalent typhoid vaccine. No explanation of this obvious lowering of protective antibody content is offered, but it is thought to be connected in some way with the multiplicity of reaction-provoking substances in T.A.B. vaccine simultaneously administered, as contrasted to the relatively fewer of such substances present in monovalent typhoid vaccine.⁸

COMMENT: These results (Table 3) are characterized by comparatively low protective titers, when expressed as m.l.d.'s of the test organism. They are difficult of interpretation because of the relative avirulency of the test organism, necessitating the administration of enormous numbers of organisms in the challenging doses. And, if the causal organism, in an actual epidemiological situation, were not any more virulent than the test organism used in these tests, the degree of immunity would require restatement in some term other than "m.l.d."

However, replacement of *S. paratyphi* 41-N-8 by the more virulent strain 41-N-22 has, apparently, resulted in the production of a higher average *S. paratyphi* protective titer.

higher than that of the 1940 group, and it is possible that this factor may have influenced the production of comparatively higher titers by the present T.A.B. vaccine.

Cross-immunization against Heterologous Types of Salmonella—Sera of individuals initially vaccinated with T.A.B. vaccine were similarly titrated against various types of *Salmonella*. It was found that significant amounts of protective substances could be demonstrated in such sera, active against *Salmonella typhimurium*, *Salmonella enteritidis*, and against the Java strain of paratyphoid B, but not against *Salmonella choleraesuis* nor *Salmonella oranienburg*; nor were there any demonstrable protective substances active against *Proteus morgani*—an organism

COMMENT: The potency of T.A.B. vaccine containing *S. paratyphi* 41-N-22 (Table 4) seems to extend its improved quality to protection against *S. schottmuelleri*. However, it will be noted that the intitial or "natural" immunity of this group of individuals is, in general,

of questionable etiological significance in diarrheal diseases, classified at one time with the *Salmonella* but later withdrawn because of its antigenic alienage. From these results, it appears that T.A.B. vaccine may be considered an effective immunizing agent against cer-

tain types of *Salmonella* which are antigenically related to the vaccine organisms, but not against the "Suipestifer" or paratyphoid C (O-antigens VI-VII) group of *Salmonella* nor against the antigenically unrelated *Pr. morganii*.

Cross-immunization against Strains of Coliform Organisms containing Salmonella Antigens—Two strains of coliform organisms, each containing a different group of *Salmonella* antigens, were obtained from Dr. Philip R. Edwards of the National Salmonella Center in Lexington, Ky. One of these was designated "Coli Fla. 573," and contained O-antigens I and II (as in paratyphoid A); the other was labeled "Coli 3," and was endowed with O-antigens IV and V (as in paratyphoid B). Although neither of these organisms had been indisputably incriminated as the causal organism of an enteric infection, "Coli 3" was thought to have caused

such a condition, based on the absence of any other etiological agent in the stools of the patient and on a significant paratyphoid B agglutinin titer of the patient's serum. Strain "Coli Fla. 573" was as virulent for mice as the more active strains of *S. paratyphi*, its m.l.d. being 1 million organisms in 5 per cent mucin. The "Coli 3" culture was highly virulent for mice, its m.l.d. in mucin being between 100 and 1,000 organisms.

It had previously been learned⁷ that these organisms were loosely connected immunogenically with their paratyphoid simulants; that is, "Coli Fla. 573" was capable of evoking a low degree of immunity to paratyphoid A, and "Coli 3," prepared as a vaccine, produced a somewhat higher degree of immunity to paratyphoid B. It was then desired to learn, in the event these coliform organisms were actually pathogens, whether

	No. of Persons	Per cent	No. of Persons	Per cent
100,000	22	53.65
10,000	17	41.46
1,000	8	19.51	2	4.87
100	25	60.97
10	8	19.51
Totals	41	99.99	41	99.98

any demonstrable protective substances active against them were produced in persons inoculated with T.A.B. vaccine. Serum protection tests were therefore performed with the sera of persons initially vaccinated with T.A.B. vaccine, using "Coli Fla. 573" and "Coli 3" respectively as test organisms. The results of these determinations have been recorded in Tables 5 and 6.

COMMENT: Vaccination of humans with T.A.B. vaccine (Table 5) produced demonstrable protective substances active against this coliform organism containing paratyphoid A O-antigens I and II; but, as in the case of serum protection tests against *S. paratyphi*, interpretation of results is difficult because of the relative avirulence of the test organism and the necessity for administering enormous numbers in the challenging doses.

COMMENT: These results (Table 6) indicate that vaccination of persons with T.A.B. vaccine produced significant quantities of protective substances in the blood serum of these individuals, active against the coliform organism containing paratyphoid B O-antigens IV and V. It is interesting to note that, as in the case of titration of these sera for paratyphoid B protective substances, the titers of the sera collected before vaccination are relatively high.

Interest in these coliform organisms is centered around a statistical analysis of the incidence of enteric infections, made in 1937 by Callender and Inmon.⁹ These observers noted that a significant drop in the morbidity of all diarrheal diseases in the United States Army followed, by some months, the introduction of *S. schottmuelleri* in typhoid vaccine, and that an equally significant increase in these diseases followed the withdrawal of the Para B fraction from T.A.B. vaccine. They realized that "the antigenic factors in typhoid [and paratyphoid] immunization by the U. S. Army may have an influence on the

morbidity of diarrheal diseases . . ."; and, referring to the apparent correlation between changes in morbidity and changes in the components of enteric vaccine, they added: "Whether this series of events is due to immunization or not, the coincidence is striking."

Members of genera of the family *Enterobacteriaceae* other than the *Salmonella* are, of course, responsible for much of this heterogeneous group of "diarrheal diseases." Coliform organisms have often been suspected of having some etiological significance, but have never been definitely incriminated as causal organisms of human enteric infection; and even more often, probably, these organisms have escaped attempts to incriminate them solely because of their coliform cultural characteristics.

One instance of the reverse of this was brought to our attention about a year ago—that is, an instance wherein the cultural characteristics of an organism were overlooked (or not determined), the culture being hastily typed with diagnostic *Salmonella* sera and reported as *S. paratyphi* because of its high agglutinability by Para A serum. Later, this culture was found to ferment lactose slowly, and it was subsequently identified as a coliform organism containing Para A antigens.

The question arises—How often, if this latter procedure were followed, would coliform organisms, suspected of playing an etiological rôle in diarrheas, be found to contain *Salmonella* antigens? And this suggests another question: Are these particular coliform organisms the only—or the most common—representatives of the *Escherichia* capable of producing enteric symptoms in man? If so, the connection between morbidity of diarrheal diseases and the antigenic content of enteric vaccines becomes evident. A potentially productive field for investigation of this type of enteric infection is open to the epidemiologist.

SUMMARY

Studies have been presented on the special problems involved in the selection of desirable vaccine strains of organisms comprising T.A.B. vaccine, and on the production of circulating protective substances by vaccination with T.A.B. vaccine.

The apparent relationship of typhoid-paratyphoid immunization to the morbidity of all diarrheal diseases in the United States Army has been briefly discussed.

Vaccine strains of organisms were chosen on the basis of their virulence for mice on the one hand, and for their immunogenic potency as demonstrated by active immunization of mice, on the other.

Initial vaccination of young adult males with T.A.B. vaccine produced significant amounts of protective substances in the blood serum active against *E. typhosa*, *S. paratyphi*, *S. schottmuelleri*, the Java strain of paratyphoid B, *S. enteritidis*, *S. typhimurium*, and against two coliform organisms containing *Salmonella* O-antigens I and II, and IV and V, respectively. Such vaccination failed to produce, by the method used for detection, demonstrable protective substances active against *S. choleraesuis*, *S. oranienburg*, and *Pr. morganii*.

Replacement of the originally selected strain of *S. paratyphi* as the Para A component of T.A.B. vaccine with a relatively more virulent strain of this organism was followed by a general improvement in the potency of the combined product, as evidenced by significantly higher protective titers for

E. typhosa, *S. paratyphi*, and *S. schottmuelleri*.

Coliform organisms containing *Salmonella* antigens offer an interesting group of possible etiological agents for study, particularly in view of the antigenic and immunogenic relationship between these and the T.A.B. vaccine organisms. It is probable that, if coliform organisms suspected of causing or inciting enteric infections were typed with diagnostic *Salmonella* sera, many more of such antigenic relationships would be revealed.

ACKNOWLEDGMENTS—We are indebted to Colonel George R. Callender, M.C., Director, Army Medical School, for his interest, suggestions, and helpful criticisms in this work; and to Dr. Mario Mollari, Professor of Bacteriology and Preventive Medicine, Georgetown University Medical School, for securing the cooperation of medical students as subjects for vaccination and as a source of test material.

THE USE AND ABUSE OF EPIDEMICS or THE SYLLOGISTIC BLITZKRIEG

IN these days of rationing, an unwanted health official must be removed from office by some means other than choking him to death with butter. Of the substitute measures available, one of the most effective and at the same time least suspected by the public, is what may be called the *syllogistic blitzkrieg*. In applying this devastating procedure, one needs only to generalize along seemingly sound lines, then with some fanfare and drama, to go from the general to the particular, thus: (1) The occurrence of an epidemic is evidence of the incompetence of the health official having jurisdiction; (2) an epidemic has occurred in Dr. John Smith's jurisdiction; (therefore) (3) Dr. John Smith is incompetent.

The major proposition here is one that might be true in a particular instance, but as it cannot be applied in all cases, it is not a sound premise. However, it can easily be brought to focus in the public mind, and in expert blitzkrieging, it is seldom necessary even to state it. About all that one need do is to furnish the second or intermediate step: "An epidemic has occurred in Dr. John Smith's jurisdiction." Give this some publicity, with perhaps a few indignant letters to the newspapers, and, bingo, Dr. Smith's incompetence is established beyond peradventure of doubt, and out he goes: And all this without scrutiny of the major premise or, for that matter, without inquiry as to whether or not an epidemic really exists.

The effectiveness of the technic depends upon the fact that, though the man on the street is not likely to be able to define a syllogism, he is fond of putting two and two together and thus tends to reason along these deadly lines. This is a fine thing for a democracy, as long as the ability to recognize two and two does not require any special training or technical knowledge. If that necessity does arise, then the whole syllogistic process becomes highly dangerous, for there are millions of false premises lying around loose and one may, by mistake or design,

use such propositions to prove that all cats have two tails, or that white is black, or that a health official is a most incompetent fellow.

All of this leads to a declaration that we are not happy about a recent sequence of events in the Mental Hygiene Commission of New York State. These events, in effect, were as follows: (1) There broke, in the newspapers, a story that there was an outbreak of amebic dysentery in the Creedmore (psychiatric) State Hospital. (2) An investigating committee reported conditions as distressing and there was a great furore. (3) The Commissioner of Mental Hygiene "retired." (4) The state law was changed so that it will permit choice of a mental hygiene commissioner solely for his ability as an administrator.

The retiring commissioner may or may not have been incompetent. That is not the issue. The disturbing thing is that amebic dysentery in a psychopathic population was the criterion used to determine competency. In such an institution, with depleted help and with patients in many instances serving as attendants, one may not expect the amebic dysentery case rate or carrier rate to be as low as in normal persons living normal lives. To be astonished that it is higher is, from an epidemiological standpoint, on a par with astonishment that there are more tombstones in a cemetery than in a victory garden. And because it is misleading to count carriers of *Entamoeba histolytica* cysts as cases of amebic dysentery, epidemiologists, in this particular instance, would be interested in knowing just how rates were calculated. Was the outbreak made up of newly discovered and currently occurring cases of amebic dysentery, or was its substance to be found in data from a stool survey, with detection of carriers? The two things are quite different. One wonders, too, how the new law permitting appointment of a mental hygiene commissioner "solely for his ability as an administrator," will lessen the amebic dysentery carrier or case rate in this institution, or in others, if looked for in the future. The sane and unemotional New York Academy of Medicine did not think this change in the law wise, and opposed it in a letter to the Governor.

Finally, we should like to know if the conclusions reached in this episode were on the recommendation of those experienced in public health administration and epidemiology. We are inclined to doubt it; and though conceivably the action taken may have been prompted by the purest of motives, the sequence of events bears many of the earmarks of the syllogistic blitzkrieg. New York is one of the great states of the Union. For many years its governors have set, for those in other states, a fine example in the way they have dealt with public health problems. It is to be hoped that this well earned and nationally valuable prestige is not to be impaired.

GRASS ROOTS HEALTH EDUCATION

THERE came into our hands a short time ago the February number of *Health Briefs* published by the Tennessee Department of Public Health. This issue is given over almost entirely to the report of health education work done by a class in a Negro junior high school in one of the larger cities of the state.

This report is a live document, a sound one, a significant one; and whoever laid out this piece of work tapped the very grass roots of common sense. That this is so is evidenced by the opening statement of these quite young students:

"We . . . wish to make our 'essay' as practical as possible. We shall confine our discussion to the four topics: (1) What people know about tuberculosis. (2) What people don't know about tuberculosis. (3) What facts students consider the most important. (4) What needs to be done about it."

And then, *mirabile dictu*, they did an amazing thing. They actually went out and learned what people know and don't know about tuberculosis. But before doing this they charted their course. They defined their terms. They practised interviewing. They listed questions to be asked and, in order to avoid bias and misinterpretation in answers to their questions, they decided to write every reply in the exact phraseology used by the persons interviewed. They asked, "What do you think tuberculosis is?" and received replies varying from, "Honey, I don't know what it is" to "A disease caused from drinking and dancing." Sixty per cent of those questioned believed tuberculosis to be inherited and only 25 per cent were of the opinion that it could be cured.

Another question asked was, "Do you believe there is any medicine that will cure tuberculosis? If any, what medicine?" The report states that there were many correct answers to that question and this is encouraging; but encouraging, too, and of interest is this statement by the students, ". . . our emotions upon reading the answers ran from surprise, disgust, amazement, and approval to pity." This is quite understandable in view of some of the answers: "Make a stew of rich fat dog," "There is a little black pill that you get at the drugstore," "I know a lady who ate 1,966 eggs in one year and drank one-half gallon of milk a day. She got well." (Ah there, Health Educators!)

Analyzing their findings, considering them in terms of age-range of persons interviewed and by occupation and educational background, these junior high school pupils went on to express what they thought ought to be done in providing public health education in regard to tuberculosis. "Through this survey and class discussion we concluded that there were certain things which would increase the general information about tuberculosis, reduce, and in time eradicate this terrible disease." They then presented conclusions which, coming from the firing line as they do, represent tactics rather than strategy, but are shrewd and sound within their limitations.

Here is no second-hand perusing of abstract information, no dallying with esoteric terminology. On the contrary, it represents a serious and direct approach to an actual and serious problem. We wish there might be more of this sort of thing in health education. We give it the title "grass roots health education" not because it comes from a state where the grass is very beautiful but because it goes deeply into the soil in which health education must grow.

LETTERS TO THE EDITOR

TO THE EDITOR:

The letter from Mr. H. M. C. Luykx published in the April issue of the *American Journal of Public Health* raises several interesting questions.

A numerical expression such as 12.2 ± 1.1 is certainly subject to misinterpretation. A brief poll among my colleagues here in the Census Bureau indicates, indeed, considerable difference of opinion as to the likely meaning of a value given after the \pm sign if presented without explanation. In spite of this fact I doubt if it is possible or desirable to eliminate the use of the \pm sign because of the economy of expression which it permits. This is particularly the case in tabular presentation. The consensus here is that, if clearly defined in the article, the notation is useful and that in the more recent American statistical literature it is now customary and acceptable to give the value of the *standard error* after the \pm sign. However, in certain statistical presentations it might be desirable to give some multiple of the standard error to indicate the complete range of values corresponding to a probability value determined by the criterion of significance.

Attention should be called to the confusion which might result from the fourth paragraph of Mr. Luykx' letter. This paragraph discusses the possible

range of sample mean values for all possible hypotheses regarding the "true" or population mean value. Except in special cases the statistical investigator is not interested in the overall range of possible sample values for all acceptable hypotheses, but rather in the range of the hypotheses themselves. The investigator is interested in the "true mean incubation period" and, using Mr. Luykx' figures and probability limits, this might well be within the range from 8.9 to 15.5 days. That is to say, the obtained mean value of 12.2 days is not incompatible with the hypothesis that the "true" mean incubation period is 8.9 days, nor with the hypothesis that the "true" mean incubation period value is 15.5 days, nor with the hypothesis that it is some stated number between these limits. To suggest that "... one should not be surprised to find an average anywhere . . . between 5.6 days and 18.8 days" obscures the fact of greatest interest, namely, that the population mean value probably lies between 8.9 and 15.5.

March 27, 1943.

FORREST E. LINDER, *Assistant
Chief Statistician for Vital
Statistics, Bureau of the
Census, Washington, D. C.*

TO THE EDITOR:

It must be true that some persons will misunderstand the meaning of "plus or minus" or the sign \pm . Mr. Luykx' point is that statisticians will not know whether reference is to the probable error or to the standard deviation; and that non-statisticians may

regard the sign as referring to the highest and lowest values.

It is not my impression that readers of the *Journal* with any statistical training would interpret \pm as indicating anything but the probable error. Certainly the textbooks and

literature in our field generally give this interpretation.

That the uninitiated might misunderstand the \pm sign is perfectly true, and it would therefore probably be best to write, for example, "standard deviation (or S.D.) = 1.6," or if the writer insists, "probable error (or P.E.) = 1.1," the probable error being .6745 times the standard deviation.

Even so, I am not sure that in re-proving the *American Journal of Public Health*, Mr. Luykx is spanking the right baby. After all, this *Journal*

merely quoted the *Journal of the A.M.A.* Moreover, the responsibility for reforms of this type can more reasonably be placed upon statistical groups, teachers, and textbooks writers. It would hardly do for the *Journal* to say in effect to its contributors, "Now you go to your room and write so-and-so-many times, 'Use S.D. or P.E. instead of \pm .'"

March 24, 1943.

A. W. HEDRICH, *Chief, Bureau of Vital Statistics, Maryland Department of Health*

TO THE EDITOR:

I have read Mr. Luykx' letter with much interest. I agree with him that the plus or minus symbol attached to a mean will not be very enlightening to readers untrained in statistics. I am inclined to believe, however, that these readers skip over such items with the greatest of ease and only readers who have been exposed to courses in statistics at one time or another notice these pluses and minuses at all. For them and their amnesias the author should not be blamed. It would be well, however, to place a P.E. (probable error) or an S.E. (standard error) after the symbol in order to insure the exact meaning.

Mr. Luykx' letter raises two points, however, which cannot be dismissed so lightly. First, he, as well as the author he quotes, accepts a normal sampling range for a biological fact such as "incubation period" which may have a range quite different from what normal sampling theory would call for. Since there is surely a lower biological limit to the incubation period, the mechanical application of standard error theory to mean incubation period, especially when the sample is rela-

tively small, may result in the paradox of including biologically impossible events within the range of statistical probability. Examples of actually impossible events made probable by erroneous statistical methods are not hard to find. If the death rate for a given disease is, say $.95 \pm .05$ S.E., we should conclude statistically that the odds are 19:1 that the true death rate lies somewhere between 85 and 105 per 100!

A second point raised by this letter is the procedure of assuming that the sample mean is equal to the true mean. This is an outmoded way of regarding the problem and can lead only to erroneous results. We do not need to make this assumption and furthermore, we cannot. We can, however, conclude the following: If the observed mean is 12.2 and the standard error is 1.1, then it follows that it is more probable that the true mean will lie somewhere between 12.2 ± 1.1 S.E. rather than outside of these limits. In fact, it will lie within these limits 68.26 per cent of the time (or odds of 2:1) and between $12.2 \pm 2(1.1)$ S.E. 95 per cent of the time (or odds of 19:1) and so forth. This is all we can deduce from

the given data. We can, however, test any hypothesis that may be proposed about the true mean. For example, if there is cogent reason to assume that the true mean is 12, we can conclude that the observed sample is not an abnormal sample, for the difference between the observed and true mean in that case is only .2 which has a critical

ratio of $.2/1.1 = .18$, and consequently is not significant.

March 23, 1943.

JOSEPH ZUBIN, *Associate Research Psychologist and Instructor in Psychiatry, New York State Psychiatric Institute and Hospital*

TO THE EDITOR:

While seconding Mr. Luykx' objections to the reference in your January issue to an average incubation period of "12.2 *plus or minus* 1.1 days," I should like to go further and risk charges of treason to my profession by inquiring why in this case any reference should be made to an *average* incubation period.

The article to which reference is made (A. E. Casey, The Incubation Period in Epidemic Poliomyelitis, *Journal of the American Medical Association*, 120, 11:805 (November 14), 1942, contains a table from which the following interesting facts can be derived:

1. In none of a series of 37 secondary cases of poliomyelitis were prodromal symptoms observed prior to the 5th day after exposure to the primary case.

2. The onset of symptoms occurred in every case but one during the 5th through 22nd days after exposure, with no very pronounced concentration of cases at any point within that interval.

3. In a single case the onset of symptoms was observed 35 days after exposure.

As a layman whose information about poliomyelitis comes almost wholly from newspapers and announcements of Birthday Balls, and as a pragmatist who has messed about in various kinds of statistics, I would infer from these findings that a child suspected of having had a single exposure ought to be watched carefully for symptoms during the period indicated. I should also

infer that the case in which the incubation period appeared to be 35 days might warrant further investigation if possible to discover any peculiarities in the patient's characteristics, history, or environment which might hypothetically be associated with the unusually long incubation period.

For purposes of comparing Dr. Casey's data with other series of observations, conventional measures of central tendency and dispersion might be useful, but in drawing practical conclusions from this particular set of data the mean and the standard deviation are by themselves almost useless and likely to be misleading. It would indeed be profitable, if possible, to evaluate statistically the chances of encountering an incubation period of less than 5 days or more than 22 days; but the author of the article has not seen fit to do this and I do not believe that he would have been justified in doing so in view of the small number of non-normal distribution of his cases.

Statistical methodology ought to be used as a means to understanding the universe and not as an esoteric device to fill the minds of the uninitiated with awe.

March 17, 1943.

ELBRIDGE SIBLEY, *Consultant, Division of Statistical Standards, Bureau of the Budget, Washington, D. C.*

REPORTS OF COMMITTEES

The By-Laws of the American Public Health Association provide that no standards shall be promulgated as the official and authorized judgment of the Association except with the approval of the Governing Council. Except where specifically noted to the contrary, the following reports are in the nature of progress reports from committees, most of which have had Section approval, but which have not been presented for Governing Council action, and therefore are not to be interpreted as standards approved by the American Public Health Association.

Report of the Archivist, 1942

Laboratory Section

THIS year your archivist reports first on the activities of the members of the Section as gleaned from the current literature.¹

Brigadier General Frederick F. Russell, U. S. Army, Medical Reserve Corps, received from the American Social Hygiene Association the William Freeman Snow award for distinguished service to humanity. The award was made in recognition of General Russell's work in organizing the syphilis and gonorrhea control program in the Army in the War of 1918, which was the basis of the present Army program. The two former recipients of this award were General Pershing and Surgeon General Thomas Parran of the U. S. Public Health Service. General Russell is also honored by the present generation of students in science. At George Washington University, Washington, D. C., there is the Smith-Reed-Russell Society, named in honor of Dr. Theobald Smith, Major Walter Reed, and General Russell, all former professors of bacteriology at this medical school.

Dr. George M. Sternberg, another charter member, is memorialized at the University of Michigan Medical School, where the Sternberg Medal was established in 1921. The medal is awarded annually to the student who has the

best record in the subject of preventive medicine.

Dr. Ludwig Hektoen and Dr. Joseph McFarland, two other charter members of the Section, received recent awards. To Dr. Hektoen was given the Distinguished Service Medal of the American Medical Association in recognition of the very great contributions he has made in many fields of science. Dr. McFarland, now Emeritus Professor of Pathology of the University of Pennsylvania School of Medicine, was presented the gold medal of the Strittmatter Award of the Philadelphia County Medical Society.

Brigadier General Raymond A. Kelser of the Army Veterinary Corps, and Chairman of the Standard Methods Committee on the Biology of the Laboratory Animal, received the award of the Twelfth International Veterinary Congress for distinguished service to veterinary science in the fight against livestock diseases. General Kelser's distinguished career in the Veterinary Corps dates back to the European War of 1918.

Dr. Jacob Geiger, San Francisco, received the blue ribbon and collar of the Order of Merit, Grade of Commander, of the Republic of Chile "for excellence of administration and research in solving public health problems."

Dr. Wilfred H. Kellogg, Chief of the Division of Laboratories of the California Department of Health, and credited with being the first man to make a bacteriologic diagnosis of plague in the United States, retired from his activities September 3, 1941. Dr. Kellogg was Chairman of the Laboratory Section 1934-1935.

Dr. Malcolm H. Soule, Professor of Bacteriology and Chairman of the Hygienic Laboratory at the University of Michigan, on leave of absence, acted as consultant to the Director of the Division of Health and Sanitation, Coördinator of Inter-American Affairs at the Pan American Sanitary Conference in Rio de Janeiro in September. He is remaining in South America until the end of November investigating the activities of the Division in that continent.

There is recorded with deep regret the death of the following members of the Section since the last report:

- L. T. Clark, D.Sc.
Detroit, Mich. Elected Member 1919,
Elected Fellow 1931.
- Carlos Manuel Garcia, M.D.
Habana, Cuba. Elected Member 1936.
- Justus Goslau, M.D.
Cedar Grove, N. J. Elected Member 1938.
- Clifford B. Line, D.V.M.
Lansing, Mich. Elected Member 1940.
- Emerson Megrail, M.D.
Cleveland, Ohio. Elected Member 1919,
Elected Fellow 1924.
- Joseph E. Pollard, M.D.
Newark, N. J. Elected Member 1924.

Last year a special plea was made for documents that have formed part of the official transactions of the Section and that should be preserved for official reference—a plea addressed in particular to the officers, committee members, and referees. Each official should leave a memorial of all the important proceedings that occur during his office. Obviously, the archives cannot be a depository for accumulated correspondence and records. Each contributor

should select the material of value in his possession and as it ceases to be in current use, deposit it; that is, convert it into archives as regularly as possible and thereafter leave it undisturbed. The Council took immediate cognizance of this situation by action aimed to facilitate the deposit of pertinent material, but since nothing has been received, it would seem that your archivist must begin a campaign to collect this material.

There is no occasion to make routine deposit of all published reports, but unpublished data, as, for example, record of the work of the Subcommittee on the Educational Qualifications of Laboratory Personnel and its report to the Association's main Committee on Professional Education, should be available in the archives.² Only in this way will the records of the objectives, policies, transactions, and achievements of the Section be preserved. Depositing original material of this character in the archives interferes in no way with the office of Secretary. Indeed, if there could be developed an awareness of the archival value of each transaction and a positive responsibility in each officer to contribute to this official record of the Section, the secretary's office would be freed for current administrative transactions.

War intensifies the need for safe depository. Thus, while archives are not historical notes drawn up for posterity, the Office of Archives might, in the present situation, well become the depository of material for future evaluation and disposition, in contrast to its traditional function of receiving only completed documents. The National Research Council has made fullest preparation for a "Medical History of the War" and the Subcommittee on Historical Records has urged that physicians "make a point of keeping diaries and of preserving materials which may ultimately be useful to the

history.”³ Members of the Laboratory Section have a definite obligation in this respect. There will be unusual opportunity on all fronts for new observations and for the trial and investigation of technics under new conditions. Certain of these wartime observations will have important peacetime applications. They will contribute, for example, to the Section’s volume *Diagnostic Procedures and Reagents*, which, as the report of the Executive Board of the Association stated last year, will “inevitably become the most representative source of experience and judgment.”⁴ Other records so collected would add measurably to the archives as evidence of the activities of members of the Section and might contribute, secondarily, to the “Medical History of the War.” I offer this suggestion to the Council and Referees for active consideration.

It was the intention last year to address each member of the Section for a record of activities and contributions to the national defense. This was deferred, but now with the formal action of War

it is important that the archives include a record of its members, in whatever capacity they may be serving. It is, therefore, proposed to canvass the entire membership in the hope of securing such a record.

The office of archives should be utilized by the membership. The contribution of the Section to the expanding fields of laboratory science can never be fully evaluated unless the members develop a responsible archival sense of their activities, and deposit record of them for the study of some future historian or research worker.

AUGUSTUS B. WADSWORTH, M.D.

Report of the Chairman of the Coördinating Committee

Laboratory Section

ONCE more the chairman of the Coördinating Committee can only emphasize the essential adequacy of the reports of the various working committee chairmen.

It is noteworthy that with changing conditions resulting from our war effort there has been no lag in the recognition by our committees of the fundamental advances in our various fields of public health laboratory procedure.

At probably no other time in our national history have milk and dairy products been so well recognized for their important rôle in every phase of our economy. Their potentialities for both good and evil are almost universally recognized.

The work of our Committee on Standard Methods for the Examination of Dairy Products is thoroughly appreciated and recognized and its influence is constantly increasing. This fine result is due not only to the keen judgment and alertness of our *Chairman*, Dr. Robert Breed, but also to the success he has had in the selection of collaborators of the first rank.

It is no simple matter for any group to anticipate changes and be ready to meet new conditions which characterize the present era. The shortage of agar and the production of a type of phosphatase by thermophilic bacteria are but two of many developments our committee is well prepared to meet.

The large sales and the demand for a Spanish edition of our volume on Standard Methods are supporting evi-

dence for the truth of these statements. The decision to prepare merely a Spanish summary of the present report seems to be a wise one.

The Committee on Frozen Desserts, Dr. Friend Lee Mickle, *Chairman*, is working in close coöperation with the Dairy Products Committee.

The Water Committee is dealing with problems which are becoming more complicated day by day. With advances in our knowledge of water bacteria the *Chairman*, Dr. W. L. Mallmann, is charged with steering a safe course between pure science and practical sanitation.

The Committee on Diagnostic Procedures and Reagents has been enlarged by its *Chairman*, Dr. W. D. Stovall. This has been done for the purpose of making our volume more comprehensive. The job of selecting new referees has not been an easy one. It has been well done.

It is predicted that this committee's report has reached only the most preliminary stages of the recognition it is destined to receive.

Prior to this war the laboratory interests of even public health workers were restricted to a few chemical and bacteriological procedures. Even so, their willing dependence on their laboratories was far beyond that of the average practitioner of medicine. With the war our concern for methods of diagnosis have suddenly increased from reluctant toleration to an almost frantic demand for help. One of the reasons

for this is our broadened interest in diseases which up to now we have tucked away under the label "Tropical." Now that we have begun to think—and read with keener interest—about the history of cholera, plague, yellow fever, malaria, and typhus, we begin to wonder why we ever thought of them as tropical. We suddenly realize that they must not be placed among the things that are exclusively tropical—the things that cannot happen here—because they have happened here. And with restrictions which are becoming more necessary every day, no safe prediction can be made concerning our possible experience with them in the coming years.

The important point in this is that diagnosis of these conditions must have laboratory confirmation. Our medical schools have been criticised by government medical departments because doctors coming into the service know so little about the erroneously designated tropical diseases. A more serious type of unpreparedness is the lack of laboratories which have the trained personnel and the equipment to render the service required to recognize communicable and other morbid conditions which we practically neglected because we have thought of them as exotic.

The chairman of our committee is

well aware of our great needs in this emergency.

The Committee on Biological Products, Colonel Elliott S. Robinson, *Chairman*, has been alert during the year but active work has been restricted.

The *Chairman* of the Committee on the Biology of the Laboratory Animal, General R. A. Kelser, V.C., has been too much occupied by his official duties to do more than maintain interest in the work of his committee. One of his active Associate Referees, Dr. Paul A. Moody, University of Vermont, has prepared a progress report on the work of this committee.

An outstanding achievement of the Laboratory Section during the past year is the reestablishment of the Committee on Germicides and Other Deterrents of Bacterial Growth, under the Chairmanship of Dr. Stuart Mudd. Since his appointment, Dr. Mudd has been actively engaged in the selection of his referees and organization of the work of his committee. Since the products and procedures which will be studied by this committee are so much involved in our war effort it is predicted that the work will be facilitated rather than hindered.

A. PARKER HITCHENS, M.D.,
Chairman

Milk and Milk Products*

(Milk, Cream, Butter and Cheese)

Laboratory Section

DURING the year a special study has been started in an effort to bring about a better standardization of the methylene blue technic in routine control work. This has been undertaken by a subcommittee in preparation for a future edition of the Dairy Products Report. The subcommittee consists of C. A. Abele, *Chairman*, A. H. Robertson, H. R. Thornton, E. H. Parfitt, and W. D. Dotterer. C. K. Johns has been asked to make a comparative study of the resazurin tests and will report on his findings in the symposium (see April *Journal*, page 393).

Attention is being given to a standardization of methods for the examination of chocolate milk drinks and homogenized milk. C. C. Carson having been drawn into Army service, the work on methods of making sediment tests is being reorganized. Professor H. C. Olson has been appointed Referee for Methods of Examining Butter, and Dr. M. W. Yale, Associate Referee for Methods of Examining Cheese. Raoul F. Cowley of Cuba has been appointed a Referee, and Dr. A. de la Garza Brito is in process of being appointed a Referee to represent Cuba and Mexico, respectively. A. W. Fuchs has been asked to serve as a

Referee to assist in coordinating the standardization of laboratory and milk ordinance work.

We regret to report the death of one of the active and valuable members of the committee, W. S. Frisbie. W. A. Queen is being asked to serve as a Referee on Chemical Methods in his place.

Last year, Professor L. H. Burgwald was asked to make a survey of Laboratories to determine how many were utilizing the phosphatase test and which of the several tests in current use they had found to be the most useful. His report was given at Atlantic City in October, 1941, and later was published in the *Journal of Dairy Science*, 25:285-291, 1942. Separates were purchased and distributed to more than a thousand laboratories that use the A.P.H.A. Dairy Products Report.

STANDARD METHODS COMMITTEE ON EXAMINATION OF DAIRY PRODUCTS

Organized 1905. Reorganized 1933. Published reports: *Year Books*, 1934-1935, 1935-1936, 1936-1937, 1937-1938, 1938-1939, 1939-1940, 1940-1941. 8 volumes published: 1910, 1916, 1921, 1923, 1929, 1934, 1939, 1941.

Standard Methods for Dairy Products *

Laboratory Section

DURING the past year the sale of the 8th edition of *Standard Methods for the Examination of Dairy Products* has continued to be excellent. The original printing of 3,000 copies having been exhausted, 2,000 additional copies have been printed and are now available for sale. Recently a request has been made by Mexican members of the Association that a Spanish translation of this report be published. As this does not seem to be feasible, the committee in charge have under consideration the publication of a summary of the present report in Spanish. A

subcommittee composed of Dr. A. de la Garza Brito, Chairman; Dr. O. Costa-Mandry and Raoul Cowley has been appointed to care for this matter.

Because of the effective help given by them to the Joint Editorial Committee which had charge of the publication of the 8th edition, Dr. A. H. Robertson and Dr. S. R. Damon have been asked to study the present report, looking toward a condensation of the English text and a better coördination of the various sections of the report.

Bacteriological Examination of Shellfish and Shellfish Waters*

Laboratory Section

INTRODUCTION

THE first edition of Standard Methods for the Bacteriological Examination of Shellfish was adopted in 1920 and printed in the *American Journal of Public Health* in 1922 (vol. 12, p. 574). In 1933 the late Professor Frederick P. Gorham suggested several minor changes (*A.J.P.H.*, vol. 23, pp. 56-57). However, no action was taken until 1935. At that time Dr. C. A. Perry was appointed referee under Dr. Robert S. Breed's Committee on Examination of Dairy and Food Products.

A questionnaire was sent to all interested persons, dealing with different aspects of a bacteriological procedure. The answers were carefully compiled and formed the basis of discussions held at the Army Medical School in Washington in April and November, 1935. In addition there was a symposium on shellfish at the Milwaukee Meeting of the American Public Health Association (1935) at which time the need for revision of existing bacteriological methods for the examination of shellfish was stressed. At this meeting an editor-in-chief of a proposed treatise on shellfish was appointed with a board of four to report on such aspects as (a) the economic importance and distribution of the shellfish industry in North America, (b) the biology of shellfish in relation to sanitation problems, (c) sanitary

surveys of production areas, (d) laboratory methods for use in the sanitary control of shellfish, (e) laboratory methods for use in the control of adulteration and decomposition of shellfish, (f) toxic products in mussels and their control, (g) epidemiology of shellfish epidemics, and (h) the nutritional value of shellfish. The plans, however, for a comprehensive report on shellfish have not yet been possible of attainment.

A new trial procedure for the bacteriological examination of shellfish was mimeographed and distributed during December, 1935. It was revised and redistributed to all concerned in July and again in December, 1938. Following the meeting of the committee at Ottawa, on June 17, 1940, another revision was issued in December, 1940, and again in July, 1941. The final revision was adopted at a joint meeting of the Laboratory and Sanitary Engineering Sections of the American Public Health Association at Atlantic City, on October 15, 1941.

The procedure has therefore undergone at least six revisions between 1935 and 1941. It represents considerable effort to meet the criticisms of various individuals and groups. Those responsible for the present method are under no delusion in regard to its technical limitations and it is fully realized that improvements and changes will follow further careful study.

Since the publication of the first

* Recommended Methods of Procedure. Report of the Standard Methods Committee to the Committee on Research and Standards.

standard method, dissatisfaction with its inadequacies in the practical sanitary control of the shellfish industry has been growing. It has become apparent from biological studies of shellfish and the shellfish-growing waters that special problems are involved. Under certain conditions it is desirable to make not only a quantitative estimate of the coliform bacteria but of the relative proportion of *Escherichia coli* present.

The examination of large numbers of water and shellfish samples makes it impractical to determine the presence of coliform bacteria as required in the latest edition of *Standard Methods of Water Analysis*. More rapid and economical procedures are desirable and, since there is no direct plating medium of practical value in estimating the numbers of coliform bacteria, the committee has recommended the estimation of the number of these organisms in the product from the results obtained by inoculating several tubes of medium with varying dilutions of the product on test. The Most Probable Number (M.P.N.) is considered mathematically more accurate and less likely to give erroneous interpretations than the "Score," and therefore tables for determining the M.P.N. have been included as the best method of expressing the results.

Two rapid methods of confirming the presence of *Escherichia coli* are recommended. The first requires plating out on eosin-methylene-blue agar (E.M.B.) and confirming on Koser's citrate medium. The second provides a transfer from the original positive lactose broth tubes to modified Eijkman lactose medium. Dodgson in England and Perry in this country have found the latter test of particular value in the practical control of the shellfish industry. Either method is sufficiently accurate to warrant practical use.

Both *Escherichia coli* and other coliform bacteria have been found unevenly distributed in the shell liquor, body and

intestine of oysters. It has seemed advisable, therefore, to use the entire oyster. A new method of cleansing and disinfecting the shells has also been introduced. Of particular importance is the examination of both shellfish and their growing waters in a comparable manner. Other changes will be noted.

The committee is deeply grateful to all those who have helped in the preparation of this procedure, for, without their criticism and advice, progress would have been impossible.

Shellfish Defined—The term "shellfish" as here used refers to oysters, soft-shell clams, quahaugs, and mussels.

Coliform Group—For the purpose of examination of shellfish and shellfish-growing waters, the *coliform group* shall be considered as including all organisms which, upon transfer from a positive presumptive test (gas positive in lactose broth), show fermentation with gas formation in lactose medium containing 0.00133 per cent of brilliant green and 2.0 per cent of bile (brilliant green lactose bile broth).

For the purpose of this report *Escherichia coli* shall be considered to be any member of this group which *in pure culture* fails to grow in Koser's citrate medium within 24 hours, or which shows definite gas formation in modified Eijkman medium incubated at 45.5° C.

I. BACTERIOLOGICAL EXAMINATION OF SHELLFISH-GROWING WATERS

Collection and Transportation of Sample

Samples of water from shellfish-growing areas should be collected at various stages of the tide and should also be collected at different depths if there is any indication of variations in salinity or pollution due to stratification. The samples should be collected in sterile bottles and should be fully protected against contamination both during sampling and after collection. They should be kept at a temperature at or below

10° C. (50° F.) and should be examined as soon as possible after collection. Every sample should *preferably* be tested within 12 hours from the time of collection and in no case should samples which have been held for more than 30 hours be tested.

Field Record

A record of environmental conditions made at the time of collection of the sample should accompany all water samples collected during the course of a survey to establish the sanitary condition of shellfish-growing waters. This record should include the following essential information:

Date and hour of collection
Exact location of the sampling station

Where possible the following supplementary data should be obtained in order to interpret the bacteriological findings:

1. State of the tide
2. Direction and velocity of currents
3. Direction and velocity of wind
4. Temperature and density of the water
5. Depth of the water and depth at which the sample was collected
6. Temperature of the air
7. Notes on any unusual conditions which may affect the sanitary quality of the water
8. Record of rainfall in the immediate past

A suitable form to be used for reporting this information may be found in the Appendix.

Procedure

Examinations for bacteria of the coliform group shall be made by primary inoculation into plain lactose broth (see Appendix) with incubation at 37° C. After incubation for not more than 48 hours definite gas formation shall be recognized by the presence of visible gas in the upper end of the inverted fermentation tube or by the presence of effervescent gas bubbles visible only when the tube is shaken.

1. Inoculate—

- a. Not less than 3 tubes with 10 ml. of undiluted water
- b. Not less than 3 tubes with 1 ml. of undiluted water
- c. Not less than 3 tubes with 1 ml. of a 1 in 10 dilution of water

(These dilutions may be altered to suit the degree of contamination of the water.)

Incubate tubes for 18–24 hours. Observe gas formation in each tube.

a. *Gas present*—Any amount of definite gas constitutes presumptive evidence of the presence of coliform bacteria and must be confirmed as described in step 2 below.

b. *No Gas*—Incubate negative tubes an additional 24 hours making a total of 48 hours' incubation. Observe gas formation.

1. Gas present in any amount constitutes a doubtful test which must always be confirmed (step 2).
2. Absence of any gas after 48 hours of incubation constitutes a final negative test.

Confirmation—A. Coliform Group

All positive gas tubes must be confirmed for bacteria of the coliform group.

2. Transfer a loopful (3 mm. diameter loop) of culture from the positive primary lactose broth fermentation tube to one of brilliant green lactose bile broth (see Appendix).

- a. Any amount of definite gas formation within 48 hours at 37° C. constitutes a positive test for bacteria of the coliform group.
- b. Absence of gas after 48 hours' incubation constitutes a negative test for bacteria of the coliform group.

B. *Escherichia coli*

Method I:

3. Inoculate eosin-methylene-blue (E. M.B.) agar plates (see Appendix) from positive lactose broth tubes which have

gas present. Incubate at 37° C. for 24 hours.

4. Inoculate tubes of Koser's citrate medium (see Appendix) with a bacteriological needle from several colonies suggestive of *Escherichia coli*. The greatest care should always be exercised to secure apparently pure cultures by using only well isolated colonies. Only a trace of the colony should be transferred, otherwise too much nutrient material may be provided. Incubate at 37° C.

Absence of growth after 24 hours constitutes a positive test for *Escherichia coli*.

Method II:

5. Inoculate tubes of modified Eijkman lactose medium (see Appendix) with a loopful of culture from primary lactose broth tubes which have gas present. Incubate at 45.5° C.

Any amount of definite gas formation within 48 hours constitutes a positive test for *Escherichia coli*.

Method III:

6. Complete all tests for *Escherichia coli* according to the recommended procedures in the appendix to the *Standard Methods of Water Analysis*.

II. BACTERIOLOGICAL EXAMINATION OF SHELLFISH

Collection and Transportation of Sample

In general, ten or more oysters, clams, or mussels judged to be representative of the lot and of the average size of the lot under examination, with deep bowls, short unbroken lips, and shells tightly closed, shall be selected and prepared for transportation to the laboratory.

Not less than ½ pint of shucked shellfish shall be collected for examination.

Shellfish selected as samples should be placed in a suitable sterilized container (such as a can with watertight lid or canvas bag) which shall be marked for identification. This same mark shall be

placed in its proper place on the descriptive form which accompanies the sample. All shellfish for bacteriological examination shall be handled aseptically.

Shellfish samples should be kept at or below 10° C. (50° F.) until examined, but under no condition should they be permitted to come in direct contact with ice.

A sample shall be considered unsatisfactory which has been improperly handled after collection. Samples of shell oysters should preferably be tested within 12 hours from the time of collection, and in no case should samples which have been held for more than 30 hours be tested. Samples of shucked oysters should be handled with special care and should, if at all possible, be analyzed within 4 hours after collection.

Field Record

A record of environmental conditions made at the time of collection of the sample should accompany all shellfish samples taken directly from growing waters. The record should include the following essential information:

Exact location and depth from which they were collected.

Date and hour of collection

Where possible the following supplementary data should be obtained:

1. State of tide
2. Temperature, and
3. Density of the water
4. Whether there has been heavy, moderate or very little rain during or immediately preceding the period of collection
5. Careful notes on any unusual sources of pollution such as boats, privies, sewers, pasture lands, animals, etc., which might affect bacteriological results

When samples are collected from packing plants or from the market, records shall be made of:

1. Date and hour of collection
2. Name and address of the place from which the samples were collected
3. Exact location of the water in which the shellfish were dug

4. Identification of the digger, shipper and reshipper, and the respective dates on which these transactions took place

5. Conditions of storage prior to collection of the sample

6. Sanitary conditions in the packing plant

7. Temperature at which shellfish were being held

Forms to be used for the submission of this data may be found in the Appendix.

Procedure

Preparation of Sample for Examination

1. Unopened Shellfish

a. Scrape off excessive growth and loose material from the shellfish and scrub with a stiff brush in running water of known purity until shells are clean and free of all mud, especially in crevices at junction of shells.

The hands of the examiner should be thoroughly washed with soap and water and the brush used for scrubbing the shells should be sterilized by boiling or autoclaving.

b. *Either* (1) immerse the scrubbed shellfish for 15 minutes in chlorinated water which will contain not less than 10 p.p.m. free chlorine at the end of treatment, as determined by the orthotolidine test and watch the shellfish during treatment and discard any which open and cause bubbling; rinse in water free of chlorine and of known purity, place on clean paper towels and dry in the air; *or* (2) place the clean shellfish on clean paper towels and dry in the air. Immediately before opening carefully flame the lip of the shellfish.

c. Open the shellfish with an oyster knife or other suitable instrument which has been sterilized by flaming or immersion for 3 minutes in boiling water. The point of the oyster knife can be inserted between the shells after some experience, or a small opening can be made with nibbling forceps. Cut the adductor muscle of the upper flat shell

if examining oysters and pry the shells apart just wide enough to drain off the shell liquor.

d. Drain off the shell liquor into a sterile bottle, then lay the oyster on a clean paper towel and pry the shell loose at the hinge. By holding the lower (deep bowl) shell down with the oyster knife and using the knife at the same time as a lever to pry open the upper shell, the anterior edge may be grasped with the left hand and removed with the minimum chance of contamination. The removal of the shell is the most difficult part of the procedure and calls for careful technic to avoid shell liquor running on the hands, and contamination of the shellfish.

e. Cut the body of the shellfish into approximately 10 equal pieces with scissors or oyster knife,* previously sterilized by autoclaving, flaming, or immersion in boiling water for 3 minutes, and empty into the bottle containing the shell liquor. This bottle should be a heavy-walled glass or rubber-stoppered bottle graduated at 200 ml. and 400 ml. Not less than 200 ml. of shellfish with the shell liquor should be used but, in no case, should less than 6 shellfish constitute the sample.

f. Add about a tablespoonful of sterile 5 mm. imperforate glass beads to the sample and shake vigorously 50 times, each shake being an up and down excursion of about 1 foot, time interval not exceeding 30 seconds.

g. To 200 ml. of this well mixed sample, add 200 ml. of sterile distilled water. Shake vigorously to mix the sample.

* A number of laboratories at the present time are using a mechanical disintegrator for the preparation of the shellfish samples. The committee has purposely omitted this procedure from the "Standard Methods" pending a study and standardization of available equipment. There may be considerable difficulty in obtaining this special equipment, due to the emergency. Laboratories having such equipment could make a valuable contribution for future standard methods by conducting comparative studies.

Allow the sample to settle for 2 minutes.

2. Shellfish Removed from the Shell

The examination of shucked shellfish shall be made in an analogous manner to that for shell stock, that is, 200 ml. of the sample (both shellfish and liquor) shall be added to 200 ml. of sterile distilled water after the bodies of the shellfish have been cut up as in step (e) above.

Examination for members of the Coliform Group and Escherichia coli

Examination of shellfish shall be made in a manner similar to that used for the examination of shellfish water samples.

1. Presumptive Test:

Using plain lactose broth fermentation tubes, inoculate:

a. Each of 5 tubes with 2 ml. (1 ml. of composite shellfish sample) from sample as prepared under section A.

b. Each of 5 tubes with 1 ml. from a 1 in 10 dilution of the composite sample (2 ml. prepared Sample A plus 8 ml. of sterile distilled water); and

c. Each of 5 tubes with 1 ml. from a 1 in 100 dilution of the composite shellfish sample (1 ml. of 1 in 10 dilution plus 9 ml. of sterile distilled water).

If desired, further decimal dilutions may be carried out. Incubate at 37° C. for a total of 48 hours. Examine after 24 and 48 hours for the presence of gas in the tubes.

The presence of gas in any amount, or the appearance of effervescent gas on shaking a tube, shall constitute a positive presumptive test; the absence of gas, a negative presumptive test.

2. Confirmation—A. Coliform Group

All positive tubes must be confirmed for bacteria of the coliform group, as described under Section 2, under "Coliform Group," in the procedure for the

examination of shellfish waters, by transfer to brilliant green lactose bile broth.

B. *Escherichia coli*

Confirmation for *Escherichia coli* shall be made by either of the two methods described under Sections 3, 4, and 5, under "*Escherichia coli*," in the procedure for the examination of shellfish waters, that is, *either* by transfer from the primary lactose broth tubes to E.M.B. plates and further identification in Koser's citrate medium, *or* by transfer to modified Eijkman lactose medium at 45.5° C. Any laboratory charged with the responsibility of examining samples of shellfish other than those known to have been freshly taken directly from growing areas would be well advised to complete all tests for *Escherichia coli* according to the procedure recommended in the appendix to the *Standard Methods of Water Analysis*. Such examinations may become the basis of legal action and shortcuts are not recommended.

C. Colony Counts

A standard colony count of shellfish samples has been found to be of value as an index of general sanitation and refrigeration.

Colony counts shall be made by inoculating various amounts of sample, as prepared under "Technical Procedure—A," above, into tryptone-glucose-extract-agar (see Appendix) and incubating plates at 37° C. for 48 hours.

The method of preparing plates and making the counts shall be that recommended by the American Public Health Association as a standard method for the examination of dairy products, except that milk shall not be added to the medium (*Standard Methods for the Examination of Dairy Products*, Seventh Edition, 1939).

* For tables of Most Probable Numbers see Hoskins, J. K., *Pub. Health Rep.*, 49:393-405, 1934 (*Reprint 1621*).

A 10 or 20 per cent solution of lactose in distilled water may be prepared and sterilized in the autoclave (15 lb. for 15 min., 121° C.), or by heating in an Arnold sterilizer at 100° C. for 1½ hrs. Add this solution to sterile broth (without lactose) in amount sufficient to make a 0.5 per cent lactose solution,

Collected by

tube with proper precautions for preserving its sterility, and sterilize at 100° C. for 30 min.

It is permissible to add by means of a sterile pipette directly to a tube of sterile nutrient broth enough of the lactose solution to make the required 0.5 per cent concentration. The tubes so made shall be incubated at 37° C. for 24 hrs. as a test for sterility before they are used.

2. *Eosin-Methylene-Blue Agar (E.M.B. Agar):*

Peptone	10.0 gm.	
Dipotassium phosphate (K ₂ HPO ₄) anhydrous..	2.0 gm.	
Agar	15.0 gm.	
Lactose	10.0 gm.	
Eosin Y, yellowish (2% aq. sol.)	20.0 ml.	} Certified for culture media
Methylene Blue (0.5% aq. sol.)	20.0 ml.	
Water (distilled) to make 1,000 ml.		
No adjustment of the reaction is necessary.		
Sterilize in the autoclave at 15 lb. for 15 min. (121° C.)		

3. *Brilliant Green Lactose Bile Broth* (2 per cent):

Dissolve 10 gm. of peptone and 10 gm. of lactose in not more than 500 ml. of distilled water. Add 200 ml. of fresh ox bile or 20 gm. of dehydrated ox bile dissolved in 200 ml. of distilled water. No dehydrated ox bile shall be used which has a pH of less than 7.0. Make up with distilled water to a total of at least 975 ml. and adjust the reaction to pH 7.4. Add 13.3 ml. of a 0.1 per cent solution of brilliant green (certified for culture media) in water; make up to a total of 1,000 ml. and filter through cotton.

Distribute the medium in tubes provided with inverted vials. Sterilize in the autoclave at 15 lb. for 15 min. (121° C.).

The reaction after sterilization shall not be less than pH 7.1 and shall not be more than pH 7.4.

4. *Koser Citrate Medium:*

Sodium ammonium phosphate (micro-cosmic salt)	1.5 gm.
Potassium dihydrogen phosphate (anhydrous)	1.0 gm.
Magnesium sulfate	0.2 gm.
Sodium citrate (crystals)	3.0 gm.
Water (distilled)	1,000.0 ml.
Sterilize in the autoclave at 15 lb. for 15 min. (121° C.)	

5. *Tryptone-Glucose-Extract-Agar with* *1 per cent Sodium Chloride:*

Agar, best quality, not oven dried....	1.5 per cent
Beef extract	0.3 per cent
Tryptone	0.5 per cent
Glucose	0.1 per cent
Sodium Chloride	1.0 per cent
Reaction—pH 6.6 to 7.0	

The above media may be purchased in dehydrated form from firms of known reliability. The preparation of these media should conform to directions given above. Dehydrated media are recommended in the case of Eosin-Methylene-Blue Agar and Brilliant Green Lactose Bile Broth.

Large laboratories obliged to make their own media would be well advised to run comparative tests from time to time, using one of these well known commercial dehydrated products for the comparison.

MODIFIED EIJKMAN TEST

Eijkman Lactose Medium:

It is recommended that the dehydrated medium manufactured by the Difco Laboratories, Inc., be used whenever possible since this should insure use of a medium of correct composition and affords an easy and economical method of preparation. The formula is given below:

Lactose	3.0 gm.
Tryptose	15.0 gm.
K_2HPO_4 anhydrous	4.0 gm.
KH_2PO_4 anhydrous	1.5 gm.
NaCl	5.0 gm.
Distilled water	1,000.0 ml.

The ingredients are heated until dissolved and sterilized at 15 lb. (pure steam) for 15 min. (121° C.).

A SUITABLE FORM FOR REPORTING FINDINGS

The concentration of ingredients should be constant, hence it is necessary to use medium of different concentrations depending on the amount of inoculum to be added. For use as a confirmatory medium with inoculation of a loopful of culture from primary lactose broth tubes, the proper concentration is that given in the first line of Table 1.

Incubation

Incubation at $45.5^{\circ} \pm 0.2^{\circ} \text{C.}$ for selective growth of *Escherichia coli* from other coliform bacteria, unlike incubation at 37°C. must be closely controlled. Below 45°C. other bacteria of the coliform group than *Escherichia coli* will grow while temperatures above 46°C. will inhibit *Escherichia coli*.

Because of the small optimum range of temperature, incubator thermometers must be carefully checked against a certified or standard thermometer and a regulator used which is sensitive to at least 0.1°C.

Only a good water-jacketed incubator, with outside wall insulation and preheated air, should be used. Temperature variations at various points in such an incubator have not been found to

vary sufficiently to interfere with the test. Fermentation tubes require from 1 hr. to $1\frac{1}{2}$ hrs. for the temperature of the broth to rise from that of the room to that of the incubator. This temperature lag is desirable as it apparently permits any *Escherichia coli* present to adjust themselves to growth at 45.5°C. Wire racks which separate the fermentation tubes have been found preferable to others. Wooden racks insulate the tubes and are not satisfactory.

Examination of Water and Sewage*

Laboratory Section

WORK on the proposed new edition of *Standard Methods for the Examination of Water and Sewage* shows considerable progress. Copy has been completed for the sections on: Sewage, Sewage Effluents, Industrial Wastes, and Polluted Waters.

Examination of Sewage Sludges and Muds
Microscopical Examination of Water
Microscopical Examination of Sewage
Sludge and Bottom Sediments
Bacteriological Examination of Water

Work is in progress on:

Sanitary Examination of Water—Physical
and Chemical
Mineral Examination of Water

Unless unforeseen developments arise, the complete manuscript will be ready for presentation in 1943.

Progress has been slow because of the fact that many members of the committee have other activities that must be handled as a result of the war.

It is urgent that a new edition be published soon to prevent the standards from becoming obsolete. A standard procedure should always be abreast of the times to be useful. New techniques and methods of analysis are constantly appearing in the literature. New acceptable procedures should be adopted as standard procedure as soon as the methods have been fully proved. Unless editions are frequent, incorporating new proven procedure, the purpose and function of a standard procedure is lost.

The proposed changes in procedures were presented in last year's report. No additional changes are anticipated.

* Report of the Standard Methods Committee.

STANDARD METHODS COMMITTEE ON EXAMINATION OF WATER AND SEWAGE

Organized 1899. Reorganized 1933. Published reports: *Year Books* 1930-1931, 1934-1935, 1935-1936, 1937-1938, 1939-1940, 1941-1942. 8 volumes published: 1905, 1912, 1917, 1920, 1923, 1925, 1933, 1936.

Examination of Frozen Desserts and Ingredients*

Laboratory and Food and Nutrition Sections

A REPORT on the activities and accomplishments of this committee has been published in the *Year Book* each year beginning with 1937-1938.

Although 1941-1942 has been one of the busiest and most productive years since the committee was organized in 1936, it is possible to summarize the work very briefly. No meeting of the committee was held during the year but a meeting has been held during this Annual Meeting at which the work of the committee, particularly that of the referee for chemical methods, has been reviewed and plans have been made for the future.

In the last Annual Report it was stated that three proposed methods had been prepared by his associate referees for Dr. J. H. Shrader, Referee for Chemical Methods; that these methods had been studied and criticised by several chemists; that they were being presented at that time to the Coördinating Committee on Standard Methods. With the approval of the Coördinating Committee those methods were mimeographed early this year and have been widely distributed for criticism and comment. These methods are:

Accurate Sampling for the Determination of Milk Fat of Ice Creams Containing Insoluble Particles, Such as Fruits, Nuts, and Crumbs of Pastry, Etc., by P. H. Tracy.

Determination of Milk Fat in Ice Cream and Ice Cream Mix by a Modified Babcock Technic, by W. H. Martin.

Detection of Stabilizers in Frozen Desserts, by F. L. Hart.

It was mentioned at the time of that report that other work by associate referees working under Dr. Shrader was in progress. Shortly after the 1941 Annual Meeting the committee was able to add a fourth proposed method to those already presented to the Coördinating Committee. That method was:

Determination of Per cent Overrun in Ice Cream, by P. S. Lucas.

During the year all the fundamental studies on these methods have been completed and the methods have had a wide circulation not only among members of this Association but among members of the Association of Official Agricultural Chemists, International Milk Dealers Association, International Ice Cream Manufacturers Association, Dairy Science Association, and International Association of Milk Sanitarians, and particularly among members of committees of those associations. A surprisingly large amount of comment and criticism has been received. It seemed desirable in the light of the suggestions offered that the methods be revised, and in some instances practically rewritten with changes in titling. This has been done by Dr. Shrader, and the revised methods have been considered by the committee at this Annual Meeting. Recommendations regarding them are being made to the Coördinating Committee. It was voted by the committee

* Report of the Joint Standard Methods Committee.

that the revised methods in their present form be included as supplements to this committee report so that they will be published during 1943 as "Proposed Methods" of the committee; it was also voted that they be again submitted to all interested persons in reprint form in order that criticism and comment on them may be secured by the committee while they are still in the form of "Proposed Methods."

In the last report of this committee it was stated that other work in progress by associate referees working under Dr. Shrader included the development of: (1) A modified method for the phosphatase test to apply it to frozen desserts, (2) a method for the determination of milk solids in frozen desserts, (3) a procedure for the determination of acidity of frozen desserts. It was also mentioned that a study of a method for the determination of saccharin in frozen desserts was under consideration but that no associate referee had been assigned to that project. The referee has nothing further as yet to report on these projects.

Methods have been completed for the bacterial analysis of all ingredients entering into the manufacture of frozen desserts except the stabilizers. Work is progressing on them but they present some difficult problems due to the insolubility of certain stabilizers except at temperatures above which most bacteria are killed. No new methods have been proposed during the year by any of the other referees.

Some criticism and comment has been received of the bacteriological methods that were published in the 8th Edition of *Standard Methods for the Examination of Dairy Products*. It had been expected that criticism would be forth-

coming since that was the first edition of *Standard Methods* to contain methods for the examination of the ingredients used in frozen desserts. Careful consideration has been given to those comments; as a result the bacteriological referees are considering rewriting those methods in a different form expecting that they will be much more usable when reprinted in the next edition. It is quite likely, for example, that all of the methods for the detection of special bacterial groups or species in milk and in dairy products will be assembled in one chapter in the next edition of *Standard Methods*.

Since the work of the committee is still in progress, it is requested that the committee be continued.

Preparation of Samples of Frozen Desserts Containing Insoluble Particles Such as Fruits, Nuts, Pastries

PROPOSED METHOD

The presence of insoluble particles of fruits, nuts, and crumbs of pastries interferes with pipetting of melted samples of ice cream for the determination of the fat. Some laboratories strain these out, some macerate them, and many neglect to test these products. Such products can be made smooth, homogeneous, and uniform by comminuting them in a malted milk mixer or similar device.*

I. Application and Limitations

When this procedure has been followed, the fat in the comminuted ingredients will be included in the fat determinations so that a determination of total fat rather than of milk fat is obtained. This procedure is analogous to the inclusion of cocoa fat commonly

encountered in the determination of fat in chocolate ice cream.

This procedure is not applicable in those communities where laws or regulations permit lower milk fat content in ice cream to which ingredients of an insoluble nature have been added.

II. Determination

Fill the mixer not more than one-third full with the melted sample. This requires 4–5 oz. by weight of sample. Operate the mixer until the insoluble particles are broken down into a finely divided state. The soft fruits are quickly comminuted. The harder products must be treated longer to secure the desired breakup.

To prevent churning, warm the sample above the melting point of the fat (to about 40° C. or 104° F.) before comminuting. Samples from properly homogenized mixes do not churn out. Cool the comminuted samples and collect in 400 ml. beakers.

They are now in condition for pipetting for the examination for the fat.

M. J. PRUCHA, PH.D.

* Suitable mixers equipped with large motors can be secured from the following:

Malted milk mixer:

The Stevens Electric Co., Racine, Wis.

The Bersted Manufacturing Co., Chicago, Ill.

Waring Blender:

The Redman Scientific Co., San Francisco, Calif.

Hollywood Liquefier:

The Hollywood Liquefier Corp., Los Angeles, Calif.

Determination of Per cent Overrun in Frozen Desserts

PROPOSED METHOD

The amount of air whipped into frozen desserts by the freezing process is commonly expressed as the percentage of overrun. In general, it is calculated from measurements of the volume and weight of the sample of frozen dessert in ratio to comparable measurements of the volume and weight of the mix.

I. Application and Limitation

For the proper regulation of overrun, both bulk and packaged frozen desserts must be examined. Public health and other regulatory laboratories are ordinarily interested in determining the amount of food solids per gallon in the final product which may be reduced

below the legal standard when overrun is not carefully controlled.

It is an accepted procedure to consider the weight and the volume of the melted, de-aerated frozen dessert as the weight and volume, respectively, of mix from which the frozen dessert has been made. However, the volume of the melt may contain variable and unknown amounts of air, tenaciously held by the stabilizer even after long heating, thus making the volume of the melt greater than that of the original mix. In such cases, the overrun calculation will give too low a figure.

II. Sampling

Select packaged samples in the original unbroken package directly from the hardening room of the manufacturing plant or in the storage cabinet of the dealer; immediately store them in an insulated container with dry ice, and hold them frozen in the container until they are examined in the laboratory. Optionally, an equivalent refrigeration practice may be followed.

In sampling bulk frozen dessert certain determinations must be made in the field. First weigh the original container, usually of 1, 2½, or 5 gal. capacity, together with its contents. (If the weight is less than 15 lbs., the scale used should have a tolerance no greater than ⅜ oz.; if the weight is between 15 and 50 lbs., the tolerance should not exceed ¾ oz.) If the weight of the container is not already known, remove the contents and determine the weight of the dry, empty container. (The contents should be handled in a sanitary manner so that they may be returned to a subsequent batch of mix for re-freezing.) The difference between these two weighings is the net weight of the given volume of frozen dessert.

Record the net weight of the frozen dessert that was in the container and the capacity of that container on the information sheet submitted with the

sample. Then place a sample* of no less than 8 oz. in a stoppered bottle to be taken or shipped to the laboratory.

III. Determination

A. Volume of Frozen Dessert—

To determine the volume of packaged frozen desserts follow one of the three procedures given below. The determination of volume of bulk frozen desserts has been made in the field as specified above.

1. Determine the capacity of the container up to the level of the fill of the contents by measuring the dimensions of the container; if cylindrical, the measurement should include the inside diameter and the depth from the level of the fill; if tapering, measure the diameter at the level of the fill and at the bottom, using the mean of these measurements as the average (mid) diameter. Calculate the volume from the formula

$$\text{Volume} = \pi r^2 h$$

where π is 3.1416, r is the radius, and h is the height.

2. A quicker way to determine the volume is to fill the container with water at 20° C. (68° F.) up to the level of the fill, and then measure this volume of water. In case it is not practical to empty the original container, measure the volume of several similar containers to the same fill, and average their volumes.

3. The volume of a wrapped slice or brick of frozen dessert can be calculated from its measured dimensions.

B. Weight of frozen dessert—

1. Weigh † the product the volume of which has been determined.

* The Bureau of Dairy Service, California Department of Agriculture, Sacramento, recommends the following sampling procedure: The sample of the frozen dessert is taken with a sterilized spatula and put into a 2 oz. bottle fitted with an aluminum screw cap which is sealed with a single service, removable, inner gasket of pulp board. The samples are packed in a case called a "Davis Pie Cover," which is 11 in. deep by 10¼ in. diameter, accommodating two layers of 2 oz. bottles, 27 to the layer. Two frozen brine pads are placed in the bottom of the case, and one on top. These pads are usually frozen in ice cream hardening rooms. If the brine pads are frozen solid, the samples will remain frozen for 24 hours, even under warm weather conditions. The cases are obtainable from A. E. Warwick Co., 15 Pierce St., Reading, Mass., \$16 each. The brine pads known as "Round Zero Packs," are obtainable from Waltham System, Inc., 277 Military Road, Buffalo, N. Y.

† See note on next page.

2. In the case of wrapped slices or bricks, weigh* the frozen dessert in its immediate container or carton. Remove all traces of product from the container, dry the container thoroughly, and weigh it. The difference in the two weights represents the net weight of the frozen dessert.

C. Volume and weight of mix from melted frozen dessert—

Weigh about 130 gm. of well mixed frozen

* For these weights, a Harvard trip balance, capacity 2 kilograms, sensitive to 0.1 gram, can be used.

dessert (weighed accurately to the nearest centigram) into a tared 250 ml. volumetric flask. (A 250 ml. sugar flask is convenient because of its wider neck.) Heat contents to 50° C. (120° F.) for 3 minutes to expel air. Add 10 gm. of n-amyl alcohol, sp. gr. 0.817/20° C., or capryl alcohol, sp. gr. 0.827/20° C., to break the foam. Adjust temperature of contents to 20° C. (68° F.). Fill flask to mark with distilled water at 20° C. (68° F.). Dry outside of flask and weigh.

Calculate the volume of this known weight of mix (i.e., melted and de-aerated frozen dessert) as follows:

$$(a) \text{ (weight of contents of 250 ml. flask) } - \text{ (weight of frozen dessert + amyl alcohol) } = \text{ gm. water added}$$

$$(b) \frac{\text{gm. water}}{0.998} = \text{ml. water}$$

$$(c) 250 \text{ ml.} - (\text{ml. water} + 12.24 \text{ ml. amyl alcohol}) = \text{ml. mix}$$

$$(d) \frac{\text{gm. mix}}{\text{ml. mix}} = \text{density of mix}$$

The weight of any volume of mix equals its density times its volume.

D. Calculation of overrun—

$$\frac{(\text{wt. unit volume of mix}) - (\text{wt. same volume of frozen dessert})}{(\text{wt. same volume of frozen dessert})} \times 100 = \text{Percentage overrun}$$

NOTE: 1,000 gm. = 2.205 lbs.
3,785.43 ml. = 1 gal.

P. S. LUCAS

Modified Babcock Technic for Milk Fat in Frozen Desserts

PROPOSED METHOD

I. Applications and Limitations

The need for a rapid sorting test in regulatory practice to indicate those samples of frozen desserts which need more detailed examination has led to numerous attempts to devise a modification of the relatively quick and cheap Babcock method. None of the modifications of the Babcock procedure has

received general acceptance. They are not accurate enough for court cases. However, they are so much quicker and cheaper than the official Roesse-Gottlieb method that they are used by many regulatory officials to analyze far more samples than could be handled only by the official method. The so-called Minnesoia modification¹ is the one most

widely used and is proposed here.* Any samples showing low fat content by this method should be run by the official Roese-Gottlieb method.

II. Apparatus and Reagents

Apparatus:

1. Cream weighing scales—described under Part IV, B, XXV, p. 250 †
2. Centrifuge, Babcock type
3. Dividers or other reading device
4. Test bottles, 20% ice cream
5. Water bath with rack

Reagents:

1. Sodium salicylate
2. Potassium carbonate
3. Sodium hydroxide
4. Isopropyl alcohol ‡
5. Glymol or other colored "reading" solution

The first four chemicals listed are used to make the reagent,** which may be made as follows: To a mixture of 645 gm. sodium salicylate, 355 gm. potassium carbonate, and 165 gm. sodium hydroxide add 3 liters of water. After the chemicals have dissolved, add 1 liter isopropyl alcohol. Store in cork or rubber-stoppered glass bottles.

III. Sampling

Sample frozen ice cream from the container or can by removing about $\frac{1}{2}$ –1 in. of the upper surface and taking the sample from the freshly uncovered lower layer. Sample wrapped, sliced ice cream by removing the wrapper from any slice which is representative of the total volume. Samples of stick ice

cream are obtained by trimming off outer chocolate or other coating. Ice cream mix is sampled from a storage vat after thorough agitation or from a can after thorough stirring.

Melt the frozen product in a water bath (temperature about 38° C. or 100° F.), by long storage at 5–10° C. (40–50° F.) or at room temperature. Keep the sample covered during the melting to prevent evaporation of water from the sample. Thoroughly mix the melted sample or liquid mix by pouring back and forth from one container to another just before it is weighed into the test bottles. Use care to incorporate any accumulated foam layer.¹

IV. Determination

Preferably run each determination in duplicate. Weigh 9 gm. of prepared sample into a 20 per cent ice cream test bottle. Add 15 ml. of the reagent. Shake thoroughly. Digest for 12–15 minutes in a gently boiling water bath, having the bottles in a rack held at least $2\frac{1}{2}$ in. above the bottom of the bath. Shake the mixture in the test bottle vigorously at the time when at least half the contents of the bottle have turned dark brown (usually about $2\frac{1}{2}$ minutes after placing them in the water bath). Shake vigorously again about 1 minute later. Some care may be necessary when starting to shake the bottles the second time, as the isopropyl alcohol in the reagent may boil off through the neck of the bottle, taking with it some of the mixture.

Centrifuge the test bottles for $\frac{1}{2}$ minute at the speed used for the regular Babcock test. Add hot water (55–65° C. or 130–150° F.) to float the milk fat well up into the neck of the test bottle. Centrifuge for $\frac{1}{2}$ minute. Place the test bottles in a water bath at 55–60° C. or 130–140° F. and leave for 5 minutes only, because prolonged contact may entail loss of fat by saponification.

Tests may be read with the use of a

* The so-called Minnesota modification and the so-called Pennsylvania method (*Pennsylvania State College Agr. Exp. Sta. Bull.* 412, 1941) have both been reported favorably, particularly the latter, for chocolate ice cream. Both received such favorable commendation that tentative decision to adopt the Minnesota test rests upon its greater use (as determined by circularized questionnaire and comments by collaborating laboratories). Further studies are being made on the usefulness of the two methods. The slightly preferred one is presented herewith to get the work started and to secure a volume of constructive comment.

† References in this style refer to *Standard Methods for the Examination of Dairy Products*, 8th Ed., 1941.

‡ This reagent may be purchased under name of Petronol, Isopropanol, etc.

** The prepared stable reagent may be purchased from the Kimble Glassware Co., Vineland, N. J.

colored reading fluid such as glymol, or a reading may be taken from the bottom of the upper meniscus to the bottom of the lower meniscus. If a colored reading fluid is used, immediately before reading each test allow just a few drops of the fluid to flow gently down the inside of the neck of the bottle; the liquid must not be dropped onto the surface of the fat column. Hold the bottles in a level position and read as one would read a Babcock cream test, measuring from the bottom of the lower meniscus to the sharp line of demarcation between the glymol and the fat. To secure

accurate readings, apply divider points to the smooth side of the bottle neck using care to prevent slipping of lower point of divider. When adjusting the lower point of the dividers, keep the eyes on a level with that point; and when adjusting the upper point, raise the eye accordingly. Report the average of the duplicate determinations.

W. H. MARTIN

Detection of Stabilizers in Frozen Desserts

PROPOSED METHOD

Frozen desserts may contain gelatin, gums, sodium alginate, or a mixture of any of these stabilizers. Sherbets or ices may contain pectin, or any of the foregoing products.

I. Application and Limitations

Sodium alginate differs from the true gums in that a precipitate of alginic acid is formed by the addition of trichloroacetic acid. Trichloroacetic acid cannot be used to separate sodium alginate from proteins because it precipitates both proteins and alginic acid. Tannic acid precipitates only the proteins, including gelatin, leaving the gums, including the alginates, in solution.

The proposed method involves: (1) Differential treatment with trichloroacetic acid to remove proteins and sodium alginate and treatment with tannic acid to remove proteins; (2) addition of alcohol to the filtrates to precipitate gums and any remaining alginates; (3) confirmation with special reagents.

This method does not detect pectin in sherbet. It does not tell definitely whether gelatin is present. Methods¹

for the detection of gelatin in milk which can be used on frozen desserts with little modification have been published by the Association of Official Agricultural Chemists.

II. Apparatus and Reagents

Apparatus:

1. Beakers, 150 ml.
2. Bottles, 8 oz.*
3. Casseroles, 500 ml.
4. Centrifuge
5. Centrifuge tubes, conical, 50 ml.
6. Cream weighing scales, sensitivity 30 mg. (Part IV, B, XXV, p. 250.)†
7. Evaporating dishes
8. Filter paper, Whatman 41H
9. Pipette guard‡
10. Pipettes
11. Water bath

* Some laboratories use 8 oz. nursing bottles.

† References in this style refer to *Standard Methods for the Examination of Dairy Products*, 8th Ed., 1941.

‡ The problem of pipetting the lower liquid portion of a centrifuged mixture without contamination from the top layer is facilitated by the use of a pipette guard, called a Vohale tube. (Hart, F. L., *J. Assoc. Offic. Agri. Chem.*, 20:529, 1937.)

This device consists of a wide-bore glass tube, flared slightly at the upper end and fitted at the lower end with a ground-glass cap, over-all length about $\frac{1}{2}$ in. less than that of the centrifuge bottle. The

(Cont. on next page)

Reagents:

1. Acetic acid, glacial
2. Trichloroacetic acid, 50% w/v
3. Hydrochloric acid, concentrated
4. Tannic acid, 20%
5. Sodium hydroxide, approximately 2N solution
6. Alcohol, ethyl, 95% and 80%
7. Benedict's reagent, qualitative:

Prepare Benedict's reagent as follows: Dissolve 17.3 gm. sodium citrate and 10 gm. anhydrous sodium carbonate in about 80 ml. hot water; dissolve 1.73 gm. crystalline copper sulfate in 10 ml. water. Filter the alkaline citrate solution, add the copper sulfate solution slowly, with constant stirring, and make up to 100 ml.

8. Phloroglucinol
For Tollen's test ²

III. Sampling

Sample frozen ice cream from the container or can by removing about $\frac{1}{2}$ -1 in. of the upper surface and taking the sample from the freshly uncovered lower layer. Sample ice cream mix from a storage vat after thorough agitation or from a can after thorough stirring. Remove the coating from on-the-stick samples and use all the remainder. For samples from small packages, remove about $\frac{1}{4}$ in. of top layer and use the whole contents.

IV. Determination

Weigh 100 gm. ice cream or ice cream mix into each of two 500 ml. casseroles.

(Cont. from page ahead)

tube is supported in the neck of the bottle by a slotted rubber stopper. After the material has been centrifuged, the pipette is inserted through the tube, the glass cap being pushed off, and the aliquot part desired is removed without disturbing the supernatant layer.

In lieu of this, a piece of glass tubing, 8 mm. inside diameter and about $7\frac{1}{2}$ in. long, may be used. The tube should be flared at the upper end, and a short cork stopper fitted onto the lower end. This stopper should be of sufficient size so that it does not rise up into the tube when the bottles are centrifuged. The tube is supported in the neck of the bottle by a slotted rubber stopper. After the material in the bottle is centrifuged the cork stopper is pushed through by means of a solid glass rod and the lower layer is removed by means of a pipette inserted through the pipette guard. (Hart, F. L., *Ibid.* 22:605, 1939).

Add 100 ml. hot water to each casserole. Heat to about 80° C., stirring constantly.

Transfer the contents of each casserole to an 8 oz. bottle. Add glacial acetic acid drop by drop, shaking after each addition, until separation of casein occurs. Insert a pipette guard. Centrifuge until the casein has collected in the upper part of the bottle (15-20 minutes).

Pipette as much of the aqueous layer as possible into a glass or platinum evaporating dish. Evaporate over steam down to about 40 ml.

Transfer contents of each dish to a 50 ml. conical centrifuge tube.

To one portion ("Portion A") add 10 ml. of a 50 per cent trichloroacetic acid solution to precipitate proteins and to remove the sodium alginate as alginic acid. To the other portion ("Portion B") add 10 ml. of a 20 per cent tannic acid solution to precipitate proteins.

From this point on treat "Portion A" and "Portion B" identically. Allow to stand 15 minutes. Centrifuge until precipitate has settled compactly (10-15 minutes). Decant through rapid filter paper (Whatman 41H) receiving the filtrate into an 8 oz. bottle. Add 4-5 volumes of 95 per cent alcohol. Allow to stand over night or until the precipitate begins to settle.

Centrifuge 15-20 minutes. Decant the supernatant alcoholic layer as completely as possible. Wash twice with 80 per cent alcohol, centrifuging and decanting after each washing. Care must be exercised to wash thoroughly the separated gums (or the gums and proteins) in order to assure complete freedom of the precipitate from the sucrose and/or reducing sugars originally present in the frozen dessert. These products themselves if present in the test portion will give a positive Benedict's test.

Dissolve residual precipitate in the bottle in 40 ml. hot water. Add 1 ml. glacial acetic acid. Without filtering,

add 4–5 volumes of 95 per cent alcohol. Allow the mixture to stand overnight or until the precipitate settles. Centrifuge and decant the supernatant solution. Add 30 ml. hot water to the residue. Transfer to a 150 ml. beaker. Add 5 ml. concentrated hydrochloric acid. Boil gently for 2 minutes. Test both "Portion A" and "Portion B" by Benedict's test and by Tollen's test as follows:

Benedict's Test: Transfer 1 ml. of the hydrolyzed gum solution to a test tube. Neutralize with approximately 2N sodium hydroxide solution, using litmus paper as an indicator. Remove the litmus paper. Add 5 ml. Benedict's qualitative reagent. Boil vigorously 1–2 minutes. Allow to cool spontaneously. A voluminous precipitate, which may be green, yellow, or red, indicates reducing sugars.

Tollen's Test: Heat the remainder of the hydrolyzed gum solution to boiling and drop in a few crystals of phloroglucinol. A red or deep amber color indicates pentoses. Certain other sugars (as galactose) also give a positive reaction to Tollen's test.

V. Interpretation

Sodium alginate is precipitated as alginic acid by trichloroacetic acid and is removed from "Portion A" along with the proteins. Hence when sodium alginate is present as a stabilizer, scanty precipitation or none at all occurs later with alcohol. Alginates are not affected by tannic acid and remain in "Portion B" to be precipitated later by alcohol along with gums. Some vegetable gums will appear in the filtrate after treatment with either protein precipitant.

However, locust bean gum and agar agar gum may be precipitated with tannic acid, and thus be removed wholly or partly with the proteins.³

These findings by alcohol precipitation may be summarized thus:

Portion A (trichloroacetic acid)	Portion B (tannic acid)	Interpretation
+	+	Gums with or without alginates
+	—	Gums, possibly locust bean or agar, but no alginates
—	+	Alginates, but no gums
—	—	No gums or alginates

(+ and — signs indicate positive and negative tests for sugars on hydrolysates.)

Voluminous precipitates in both "Portion A" and "Portion B" after addition of alcohol indicate the presence of gums with or without alginates.

A voluminous precipitate in "Portion A" after addition of alcohol, responding positively to Benedict's test and to Tollen's test, indicates the presence of vegetable gums, but not sodium alginate. A voluminous precipitate in "Portion B," similarly treated with alcohol, responding positively to Benedict's test and to Tollen's test, with scanty precipitate or none at all in "Portion A," indicates sodium alginate.

F. LESLIE HART

Germicides and Antibacterial Agents*

Laboratory Section

NEW germicidal agents of great potential importance for the control of communicable disease are currently in process of development and application. The Standard Methods Committee for the Examination of Germicides and Antibacterial Agents has been organized this year. Five of the eight members of the committee have papers on the program of this Annual Meeting. The present report represents, however, a statement by the chairman in regard to the membership of the committee and the scope of its activities rather than a report by the several referees on their special fields.

The achievement of a considerable measure of control over the broad categories of the *intestinal* and the *insect-borne diseases* has been a major success in public health endeavor. The infections contracted through the respiratory tract, the *air-borne diseases*, however, stand today as an unanswered challenge to those concerned with protecting the public health. The childhood contagions, whooping cough, measles, mumps, chicken pox and scarlet fever are presumably contracted through the respiratory tract; colds and upper respiratory infections cause by far the greater part of the absences from work in adults; influenza, measles and their complica-

tions have periodically, and particularly under war conditions, flared up into destructive epidemics and pandemics. No one of these major hazards from air-borne disease is under satisfactory control at the present moment, although a few far-sighted individuals are now vigorously investigating potential means for their control.

It is a great pleasure, therefore, to announce that Professor O. H. Robertson, of the University of Chicago, and Dr. Alexander Hollaender, of the National Institute of Health, have accepted membership on the Standard Methods Committee for the Examination of Germicides and Antibacterial Agents as Referees, respectively, on germicidal vapors and mists and on ultra-violet radiation for the disinfection of air.

Another new class of germicidal agents are those metabolites of certain bacteria and fungi which are antagonistic to many pathogenic microorganisms. Bacterial antagonistic substances are not only of great scientific interest, but they are already finding practical use in clearing up infections, for instance, due to sulfonamide-resistant strains. Much of the current activity in this field has originated in the laboratory of Dr. Selman A. Waksman, President in 1942 of the Society of American Bacteriologists. Dr. Waksman has consented to act as Referee on Antibiotic Substances.

Detergents, both anionic and cationic, have latterly assumed importance as practical germicides. Dr. W. L. Mallmann, of the Michigan State College, has had much experience in this field and has consented to act as Referee in it.

* Report of the Chairman of the STANDARD METHODS COMMITTEE FOR THE EXAMINATION OF GERMICIDES AND ANTIBACTERIAL AGENTS. This committee was originally authorized as the Standard Methods Committee for the Examination of Disinfectants and Antiseptics (*American Public Health Association Year Book, 1941-1942*, page 19). The change of name was authorized by action of the Coordinating Committee as better representing the scope of the committee.

In the established field of chemical antiseptics and chemical germicides, the committee is fortunate in having two referees of experience and established reputation, Dr. Henry Welch of the Food and Drug Administration and Dr. C. M. Brewer of the Department of Agriculture.

Fungous infections of the skin are a widespread source of annoyance and discomfort and under war conditions have become a serious source of disability. A refereeship on fungicidal and fungistatic agents has therefore been established and been accepted by Dr. C. W. Emmons of the National Institute of Health.

The chairman of this committee, as a member of the Council on Pharmacy and Chemistry of the American Medical Association and certain relevant National Research Council committees, has many occasions for desiring clarification of criteria and standards for all classes of germicidal agents, chemical, physical, and biological. The Council of Pharmacy and Chemistry already enjoys full coöperation with the National Institute of Health and the Food and Drug Administration. The membership of our committee of the Laboratory Section,

American Public Health Association, should aid in the coördination of ideas and information among those charged with working toward standards of safety and efficacy of all classes of germicidal agents and of working out optimal conditions for their use.

The present members of the Standard Methods Committee for the Examination of Germicides and Antibacterial Agents are:

Credit Lines

THE department "Credit Lines" is an orphan. It has been abandoned by its foster-parents most unwillingly, but nevertheless definitely, for the duration. This comes about because the successful partnership between the editors, Donald B. Armstrong, M.D., and John Lentz, has been interrupted by the departure of Captain Lentz for the armed services. Dr. Armstrong feels that he cannot cope with it alone and so returns it to the shelter from which he derived his custodial powers in the first place, the Editorial Board.

And the Editorial Board has taken it in, realizing that it cannot be maintained in the style to which Dr. Armstrong and Mr. Lentz accustomed it, but determined to do the best they can by it. The Board hopes to keep it neat, groomed, well-mannered, obliging, and helpful. Inasmuch as its personality has changed overnight, there is a suggestion that its name had better be changed as well so that any signs of neglect will not bring discredit to the previous editors. This has been worth thinking about and the thinking has resulted in a somewhat lengthy list of names from a dozen sources. Each contributor thinks his own titles are the best and yields to no one. In this stalemate, it seems wise to turn to all the relatives and ask the readers of the JOURNAL to choose the name. Those currently in command refuse to consider any additions to the list. They stand or fall on their own offerings. The rules of this contest are simple.

1. Select, from the list at the end, the title you think best describes a department whose purposes will presently be outlined.

2. Write it on a postcard with your name and address and mail the card to "Title Editor," *American Journal of Public Health*, 1790 Broadway, New York, N. Y., before midnight on June 15.

The department "Credit Lines," as it must be called until it is formally rechristened, is everybody's baby and it is hoped that many will contribute to its support. In its halcyon days, when it was the charge of Dr. Armstrong and Mr. Lentz, and in a previous incarnation when it flourished under the caption "Health Education and Publicity Notes," and the care of the late Evart G. Routzahn, it enjoyed a wide circle of readers and admirers, especially among health educators. The editorial direction was inspired, and abundantly gifted with the talent of selecting from mountains of mail, printed matter and mimeographed documents and from conversation those pithy bits and new ideas worth passing on to others. It can hardly be expected that this critical faculty, this genius for evaluating, will be found frequently again in one person or in a combination of two people even with regard to one specialty like health education. It is far less likely that one person or a team can cover all public health specialties, including health education. A lot of people, however, taking some responsibility for "Credit Lines," each exploring his own intimately known terrain, can, if they will, bring to the department a rich and diversified collection of new and original technics in public health—that is, new to the rest of us.

"Credit Lines," then, or whatever it is to be called, may be described as a

department appearing more or less regularly in the JOURNAL whose contents are decidedly miscellaneous and are brought together by a miscellaneous group. One issue may be devoted entirely to the newer motion pictures. One may contain half a dozen administrative tricks of health officers, born of ingenuity and the man power shortage. Another may present the laboratory's response to priorities and substitute materials. Still another may include short accounts of what is happening and who is making it happen in a variety of situations of interest to health workers. And the majority of issues will doubtless defy classification or over-all captioning.

Suggestions are invited. Contributions are solicited. The erstwhile "Credit Lines" is everybody's baby. What shall we call it hereafter? These are the names that have been advanced. Mail your selection today!

Specialists Pool

Several requests have been received for more information concerning the Military Government Division of the Provost Marshall General's Office. The Military Government Division is creating a pool of highly skilled men in a variety of technical and professional fields for future use in the military government of hostile areas ultimately to be occupied by American armed forces.

To be eligible for a commission in this "Specialists Pool," applicants must have had a good basic education and broad administrative or executive experience in government with a state, county, city, or federal department, or as experts in finance, education, sanitation, public welfare, public works and utilities, communications, public health, public relations, public safety, or eco-

nomics. Importance is attached to demonstrated administrative and executive ability and to knowledge of foreign countries and foreign languages. Applicants must be between the ages of 35 and 55:

Those selected will be appointed in the Officers Reserve Corps and may be called to active duty, for a period of 4 months for training, after which they will be carried in an inactive status, without pay, permitting the continuance of their present civilian activities until their services are required. They will not be subject to draft. A very small number of those commissioned may be selected to attend the School of Military Government located at the University of Virginia, Charlottesville, Va.—"On the Alert." Community Chests and Councils.

BOOKS AND REPORTS

Introduction to Psychiatry—By *W. Earle Biddle, M.D., and Mildred van Sickel, R.N.* With a foreword by *William C. Sandy, M.D.* Philadelphia: Saunders, 1943. 358 pp. Price, \$2.75.

This book is written by a graduate nurse and a psychiatrist who have tried hard and succeeded in putting before the reader a description of practical considerations that have to be met and dealt with by the relatives, friends, doctors, and nurses who are concerned with the psychiatric hospital care of mentally ill patients. I am glad that it comes from a state hospital because its presentation of facts should be of great educational value to all sorts of people who regard state psychiatric institutions as asylums instead of hospitals.

This little book answers hundreds of questions which families and doctors of families ask when psychiatric hospitalization is advised. Unit I speaks of Orientation to the Nursing Service. Unit II embraces Special Therapies in the Treatment of Psychiatric Disorders. Unit III discusses Psychiatry in Relation to Psychiatric Nursing. Unit IV gives a brief resume of Psychiatric Disorders. Unit V gives a much needed chapter devoted to Psychiatry and the Community.

This book should be in every library of training schools for nurses. It is especially useful as a practical textbook for nursing education instructors in training schools and hospitals where psychiatric nursing is part of the school program. As a teacher of psychiatry and mental hygiene for the past twenty-five years in four nurses' training schools I can truthfully say that it is a much needed book which I shall take pleasure in recommending to students and teachers.

ESTHER LORING RICHARDS

Manual of Veterinary Bacteriology—By *Raymond A. Kelser and Harry W. Schoening.* (4th ed.) Baltimore: Williams & Wilkins, 1943. 719 pp. Price, \$6.50.

The fourth edition of this well established book is welcome. Owing to the demands on his time and attention due to the war the senior author has associated with him H. W. Schoening, Chief of the Pathological Division, and Assistant Chief, of the Bureau of Animal Industry.

There are a number of notable additions and some rearrangement. The whole book has been brought up to date. There have been many advances in our knowledge of disease-producing organisms in the five years which have elapsed since the third edition, and veterinary science has shared in the general advance. We have also learned more of the diseases common to animals and man and transmissible from animals to man. These advances are well considered and presented. We need mention only the studies on encephalomyelitis to emphasize the importance of bringing these subjects up to date. It was 1939 when the Eastern type of virus was found west of the Appalachians and the Western type was found in the East. In 1937-1938 relationship between equine encephalomyelitis and St. Louis encephalitis was demonstrated, and in 1941, susceptibility of horses to St. Louis encephalitis was proved.

There are 117 pages given to the Introduction and Bacteriological Methods. The discussion on Infection and Immunity which comes next is adequate. Especially useful for the veterinary student, and too little known by the medical profession, is Part XI describing the production of vaccines, sera, antitoxins, etc.

The only criticism to be made is from the standpoint of the human physician. We believe that a little more discussion of the transmissibility of animal diseases to man would be an improvement. Under tuberculosis, for example, much more could be said about the transmission of the animal disease to human beings, especially in regard to the number of cases of pulmonary tuberculosis found in human beings due to the bovine organism. The history of the controversy is not as full as it might be, and in some places, as on page 378, there is room for a misunderstanding by people who are not careful readers of the whole text on tuberculosis. For example, under "Pathogenicity," there is not a word which would indicate that the bovine tubercle bacillus can produce tuberculosis in human beings. It is true that this is mentioned elsewhere, but certainly it should be mentioned in this place also. The authors persist in using "B.C.G." as an abbreviation for Bacille Calmette-Guérin, which is incorrect. It should be "BCG."

Altogether, the book is satisfactory and a welcome addition not only to our literature, but to the armamentarium of the teacher. It is beautifully printed on thin paper so that the 719 pages which it contains, including the excellent index, make a book of convenient size which is easy to handle and to read.

MAZYCK P. RAVENEL

Religion and Health—By Seward Hiltner. New York: Macmillan, 1943. 292 pp. Price, \$2.50.

This volume reveals an extension of applied mental hygiene into a newer field. Written by the executive of the Federal Council of Churches' Commission on Religion and Health, it brings before an audience of clergymen and other church workers a modern and constructive attitude toward behavior problems, mental illness, personal counseling, and ministry to the sick. Public

health workers will do well to be familiar with a rapidly growing movement in the churches which has enormous potentials for healthy minded attitudes toward mental and physical health. The book is commended.

REGINALD M. ATWATER

Laboratory Manual on Fundamental Principles of Bacteriology—By A. J. Salle, Ph.D. (2d ed.) New York: McGraw-Hill, 1943. 184 pp. Price, \$1.50.

This is a carefully revised second edition, with some old material discarded and valuable new procedures incorporated. The title is appropriate as the experiments are so chosen as to emphasize the fundamentals of bacteriology. The book is well adapted to the needs of students taking a general course in bacteriology, or of students of chemistry, sanitary engineering, or public health since it deals with the effects of environment upon bacteria and also with the applications of bacteriology in the examination of water, milk, and milk products, foods, and soil. The book is well printed, but will the day never come when an author will force the printer of a manual to use at least a modicum of type larger than 6 point! The laboratory exercises are unusually complete, and the contents strikingly well arranged under headings and sub-headings that follow a consistent pattern throughout the volume.

After the author has stated in the preface that this revision accompanies the second edition of his revised textbook, it is a little annoying to find in this 184 page manual the following reference appearing 94 times: "Salle, A. J., *Fundamental Principles of Bacteriology*, 2nd ed., New York, McGraw-Hill Book Company, Inc., 1942."

Especially well written directions head each exercise. The suggestions that are included should arouse interest in the experiments and serve well to

call attention to points the author rightly considers worth emphasis. Intriguing questions that follow each exercise taxed the ability of this reviewer always to answer them without resort to the frequently mentioned textbook. An appendix giving formulae for the preparation of 56 solutions and stains and 42 varieties of culture media should be of value to the student.

FRIEND LEE MICKLE

Public Health Statistics—By Marguerite F. Hall. New York: Hoeber, 1942. 408 pp. Price, \$5.50.

A simple but reliable text on public health statistics would be welcomed by health officers. The Foreword as well as the Table of Contents of the present book would lead one to expect such a volume. Unfortunately, there are so many loose and inaccurate statements both as to the subject matter of public health statistics and in the exposition of statistical methods that the book cannot be recommended either for the classroom or the reference shelf.

Space will permit only a few examples of the many misleading sentences which challenge the critical reader continuously. For instance such statements as "The country is divided into census tracts, each tract having a supervisor and assigned enumerators," in the description of the census on page 89, or "The Life Table Standard Million reflects the natural growth of population measured by excess of births over deaths" (page 139), are inaccurate. These and many similar sentences represent carelessness in expression or superficial knowledge on the part of the author.

More serious is the confusion found in the discussions of statistical technics. It is desirable that mathematical concepts be presented in simple language but the argument must remain logically sound. Many of the definitions, notations, and applications of statistical

methods are confusing. For example, in Chapter XIV, which describes the short method for the construction of the life table proposed by Reed and Merrell, the notation is badly mixed up. Further the misapplication of the method when the original data are not available to the end of life results in a half year underestimation of the expectation of life at birth with a larger error at older ages.

Lack of a fundamental understanding of random sampling, the binomial theorem, and the use of the standard error are each illustrated by the discussion of "Chances with a small sample" on page 348. This section purports to answer the question "What are the chances that 6 out of 7 potential patients actually become ill during a given month?" The remainder of the section is a jumble of words that has little, if any, bearing on the answer to the question posed. One should be able to state the solution quite simply. In fact the solution is given on page 332. Perhaps the difficulty arose first in the meaning of the statement, "in a random sampling of potential patients the chances are even for a person to become ill." Does the author mean more than that each person in a random sample is equally likely to become ill? The probability of becoming ill in a sample chosen at random is not a function of randomness but of the universe from which the sample is drawn. It is this probability or estimate of it that is represented by p in the binomial $(p+q)^n$. The vexing problem of medical care would indeed be insolvable if one half of a physician's panel were ill each month. This, unconsciously, is the author's postulate in trying to answer the above question.

Readers will find these sections and many others confusing and of little assistance in the sound application of statistical methods to the problems of public health. W. THURBER FALES

Occupational Tumors and Allied Diseases—By W. C. Hueper. *Springfield, Ill.: Thomas, 1942.* 896 pp. Price, \$8.00.

This impressive monograph presents another indication of the growing interest in the field of industrial disease. As indicated by the title, major emphasis is placed on occupational tumors, particularly epitheliomata of the skin, but consideration is also given to carcinomata of the internal organs, benign and malignant tumors of the mesenchyme, diseases of the blood forming organs, and allied conditions such as dermatoses, polyposes, and cirrhosis of the liver.

The presentation of the subject is exhaustive. Occupational tumors and allied conditions of each system are reviewed in terms of etiologic agents, frequency, pathology, symptomatology, experimental studies, causative mechanism, and preventive and medico-legal aspects. Considerable attention is paid in each instance to the chemistry of the exciting agent and the evidence provided by animal experimentation. The closing chapters are devoted to a general discussion of occupational tumors and theories of cancerogenesis.

The work can be highly recommended for its comprehensive analysis of the action of the well recognized chemical and physical carcinogenic agents and their effects on the skin, genitourinary system, and blood forming organs. In the discussion of tumors of certain internal organs, and of the relation of occupational neoplasia to theories of cancerogenesis, however, the author enters on highly speculative ground. The hypothesis is advanced that many of the internal systemic cancers are attributable to the late results of ill defined exposures to toxic chemicals but is not sustained by the statistical or experimental evidence presented. On the other hand, the effects of chronic irritation are minimized in instances such as

cancer of the lip in pipe smokers, carcinoma of the stomach associated with ulcer, and cancer of the cervix in multiparous women.

The volume is attractively printed and well indexed. The bibliography is extremely complete but would be improved by being numbered to facilitate reference to the text.

ARTHUR B. ROBINS

How to Teach Nutrition to Children—By Mary Pfaffmann and Frances Stern. *New York: Barrows, 1942.* 224 pp. Price, \$2.00.

As admirably stated in the introduction, *How to Teach Nutrition to Children* is a series of lessons to help the child understand how the food constituents—protein, carbohydrate, fat, calcium, iron, and the vitamins—build the body, furnish energy, protect health and promote growth.

The subject matter content and the method represent years of experimentation by the authors in instructing children at the Boston Dispensary Food Clinic. The authors have presented not only scientific facts about foods in their relation to health and growth of children, but the method they have found successful in the food clinics situation with children of the intermediate grade age. They have suggested stories, games, and drama to supplement the factual material. The subject matter is scientifically sound, the sources of illustrative material concrete, the charts explicit, and the applications direct. The underlying philosophy shows a deep understanding of children, of what appeals to their imagination, and the kind of handwork which impresses on their minds the facts being taught. The authors have ventured in using the metric system units to teach the daily requirement of food constituents, and are to be congratulated on their wisdom and foresight in doing so, since the metric units are being increasingly used by the lay-

man to express scientific values. Nutrition being a science, children can and should learn the proper terminology for expressing its findings.

How to Teach Nutrition to Children should be a real help to teachers in the grades, and illustrative of successful methods for educating children in situations such as the authors have met them.

MARY E. SWEENEY

Good Nutrition for Everybody—
By L. Jean Bogert. Chicago: Chicago University Press, 1942. 165 pp. Price, \$1.50.

When the food one eats becomes, as it does in wartime, a vital weapon, meals must be planned on a practical working knowledge of nutrition. When energy flags and vitality ebbs, it is difficult to be a courageous, vital, buoyant person. Both morale and efficiency rest on health, and good nutrition is basic to both. Dr. Jean Bogert knows this and also knows that good nutrition is none too easy to come by when food habits must be changed to conform to wartime markets and rationed supplies.

Good Nutrition for Everybody is a concise, simple, common sense guide to good meals in wartime. It contains no frills, no furbelows, no special diets. It is a summary of the facts one needs to know about food in order to wangle three nutritious and more or less interesting meals a day from our dwindling food supply. Dr. Bogert's practical suggestions on cooking methods are basic and good. Her emphasis is on the normal diet for the family of average means. She recognizes the difficulties involved in changing well established diet patterns but she is firm in her opinion that fastidious diets must yield to stern discipline in a world at war. Only out of a wealth of training and practical experience could material be presented so simply, so accurately.

The book contains some 123 recipes. These are more practical than interest-

ing—but so are meals in wartime. The menus suggested are planned with a patriotic regard for both time and materials. This book should be useful to anyone whether he eats at home or at a restaurant—or anyone who accepts the fact that good nutrition is built on established well documented fact.

When food is scarce, good nutrition is based on knowing, not guessing about basic food facts. One must know a few simple rules. These are carefully presented by Dr. Jean Bogert. Thoughtful people who want to know *how* as well as *why* one must cook food and plan meals carefully will find this book useful. The smaller the variety of foods on the market, the more important this type of information becomes.

The material Dr. Bogert presents in this book is concise, fairly readable, and very usable.

ELOISE DAVISON

The Sight Saver—*By C. J. Gerling. New York: Harvest House, 1943. 202 pp. Price, \$2.00.*

Written primarily for the lay public, *The Sight Saver* is a sound and practical handbook of information about the organ of vision and the possibilities for its protection. The material is arranged alphabetically, with ample cross-indexing to facilitate location of subjects under a variety of headings. Explanations and recommendations are in keeping with medical science and with the teachings of other groups whose activities are related to the preservation of eyesight. However, as emphasized by the author, the text is not intended for purposes of self-diagnosis or self-medication; the aim, rather, is to show the need for reliable and timely medical attention by giving the reader an understanding of the eye and the potential hazards of disease and injury.

Included in the extensive range of topics are the structural parts of the eye, the mechanics of seeing, errors of refraction, glasses, diseases, relation of

ocular disturbances to systemic conditions, illumination, protective devices and other factors affecting eye comfort and safety at work, at home, and at play. The respective spheres of service of ophthalmologists, optometrists, and opticians are defined, and a warning is sounded against quacks and fraudulent practitioners. Similarly, milady is cautioned in the matter of eye cosmetics, nostrums and kindred preparations purporting to enhance "the windows of the soul"; some may, at best, be utterly valueless while others may cause serious damage to vision.

Persons interested in further study of the subjects are offered a list of books and pamphlets as well as the names of agencies from which pertinent information may be obtained.

REGINA E. SCHNEIDER

Interstate Sanitation Commission
—*New York, New Jersey, Connecticut—1942 Annual Report. New York: 60 Hudson Street. 87 pp.*

The sixth report of the Interstate Sanitation Commission summarizes the commission's activities for the year, and its findings from analyses made at each of the sewage treatment works within the District. It also sets forth the progress made in the abatement of pollution in the same area.

The report contains an outline of the commission's policy which is being formulated to meet the conditions imposed by the war. The commission is taking steps to urge municipalities to develop a financial program whereby treatment works can be built when conditions permit. Municipalities are also being persuaded to prepare the necessary plans and specifications and bills of material so that they can proceed with construction without delay at the proper time.

The report describes eight locations where new treatment works have been placed in operation or major improve-

ments to existing treatment works have been completed.

A summary of analyses made of the influents and effluents of the various treatment works within the District is contained in the report. This table sets forth, among other things, the flow, hydrogen-ion-concentration, suspended solids removal, settleable solids removal, biochemical oxygen demand, residual chlorine, and the most probable number of coliform organisms. Plant performances have been rated on their ability to meet Compact requirements which are established by law. The report also contains a summary of the commission's findings concerning each of these treatment plants.

SETH G. HESS

Services to the Orthopedically Handicapped—Report of a Study under the Auspices of the Trustees of the Widener Memorial School for Crippled Children, by Louis P. Hoyer and Charles K. Hay. Philadelphia, 1942. 115 pp.

The authors studied school systems and agencies rendering services to the orthopedically handicapped in Philadelphia and a number of other cities and used the information gained in making recommendations for future planning of the services in Philadelphia, which are administered by the Board of Public Education.

As would be expected, the study and report are concerned primarily with educational services for the crippled child, but the breadth of the authors' concept of the functions of the school for the orthopedically handicapped far exceeds anything now in existence. Such a school would be the center about which all other community services for this group would revolve and would serve those on the preschool, secondary, and adult levels, as well as the elementary level. The need for these services is well brought out. Workers of all professions who are satisfied in attacking

small segments of the large field of rehabilitation of the orthopedically handicapped will do well to absorb some of the vision and philosophy expressed in this little book.

Administrators of agencies engaged in carrying out treatment programs in this field may well look skeptically on the recommendation that a corps of specially

prepared and equipped "coördinators," responsible to the Director of Education, be employed to assume most of the functions now assumed by public health nurses and medical social workers. Still another kind of professional worker in this particular area would certainly necessitate some coördination!

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Aiming toward Preventive Medicine—In Nebraska, demonstrations with two types of prepaid medical care plans are under way. In a sparsely settled region, a doctor and a nurse furnish preventive and curative services on a salaried basis to families that pay \$30 a year. In a thickly populated area, farmers pay to a central fund 6 per cent of their cash net income and for it are assured medical and hospital care, some dental care, and commonly prescribed drugs. This is a heartening story well told.

ANDERSON, E. L. Nebraska's Extension Service on the Health Front. *J. Home Econ.* 35, 3:137 (Mar.), 1943.

When Women Work—Here you will find a bird's-eye view of industrial production methods, work clothes, plant sanitary facilities, employees' meals, and health conditions outside the factory gates as they affect the 14 million and more women in industry. Every health worker worth his salt will seize every opportunity to gather in each scrap of information on this vital subject.

ANDERSON, M. Industry, Women, Safety and Health. *Am. J. Nurs.* 43, 3:275 (Mar.), 1943.

Sanity in Nutrition—Vitamin capsules speed production. Candy bars prevent fatigue and reduce accidents. Doughnuts between meals reduce absenteeism. Chewing gum with ascorbic acid works other wonders. Gum drops with salt do likewise. Crackers full of minerals and vitamins are the last word in "pep" production. These are some of the selfishly promoted dietary delu-

sions with which the industrial nutritionist must wrestle. Two papers listed here help with the answers.

BING, F. C. Criteria for the Evaluation of Nutrition Experience in Industry. (and) COWGILL, G. R. Current Nutritional Activity in Industry. *J.A.M.A.* 121, 11:813 (Mar. 13), 1943.

By the Hundreds of Billions—A statistic you may want to remember: in 1930 there were manufactured 123 billion cigarettes or 1,500 a year for every man, woman, and child over 14. Since then more and more cigarettes have been smoked. There was a 12 per cent increase during the first quarter of 1941 over the same period of the preceding year. Mentioned here is the increasing suspicion that this Himalayan heap of tobacco bears some relationship to the growing incidence of stomach ulcer.

BOWLES, R. S. Observations on the Prevention and Management of Peptic Ulcer. *J.A.M.A.* 121, 9:640 (Feb. 27), 1943.

What Would You Expect To Be the Answer?—Immunization clinics have an added educative value, the health educators are wont to insist. Three show-me investigators had the temerity to put this assertion to the test. It would be unforgiveable to spoil the story by quoting the findings here—but health educators are warned not to raise their hopes.

BRESLOW, L., *et al.* Parental and Familial Factors in the Acceptance of Diphtheria and Smallpox Immunizations. *Pub. Health. Rep.* 58, 10:384 (Mar. 5), 1943.

Hopeful Note Department—A half century hence, 15 out of every

hundred will be over 65 years of age, and this army will be better qualified for useful work than are elderly people today—thanks to more science and better art in medicine. Suitable work for our ageing population is profitably discussed.

CARLSON, A. J. The Older Worker. *J.A.M.A.* 121, 11:806 (Mar. 13), 1943.

Against One Hazard of Infancy—Evidence is presented that the immunization of pregnant women with pertussis vaccine results in transmitting some degree of protection to the newborn babies to carry them through the dangerous period of infancy when they seem especially susceptible to whooping cough. There was no discernible effect upon the progress of the pregnancy.

COHEN, P., AND SCADRON, S. J. The Placental Transmission of Protective Antibodies Against Whooping Cough. *J.A.M.A.* 121, 9:656 (Feb. 27), 1943.

More about Rheumatic Fever—Of 241 children suffering from hemolytic streptococcal infections during an institutional oral outbreak of tonsillitis, 88 had rheumatic fever. Among other findings of this study of the evident relationship between the two conditions are: familial predisposition is still an important factor; the most susceptible age group was 9–14; and the weather didn't count.

DITKOWSKY, S. P., *et al.* An Epidemic of Rheumatic Fever in a Children's Institution. *J.A.M.A.* 121, 13:991 (Mar. 27), 1943.

"Canada Approved"—Among a great many other dietary matters, there is a blessing given here to "Canada Approved" flour which produces bread almost white in color, but containing most of the valuable nutrients of the wheat berry with it, the British population will not lack for Vitamin B₁, says this authority. Apparently the British haven't our genius for taking out the natural nutrients from our food stuffs,

then putting back ersatz substitutes. No doubt they'll learn in time.

DRUMMOND, J. C. Problems of War-time Nutrition. *J. Roy. Inst. Pub. Health & Hyg.* 6, (1 & 2):26 (Jan. & Feb.), 1943.

Hygienist, Know Thyself—For a clearly told story of Dr. Kruse's studies in subclinical nutritional deficiency states among people like yourself, you will hunt far to find a better. This paper is addressed to public health nurses but its reading will do you a lot of good whatever your professional field may be.

DWIGHT, J. C. The Newer Knowledge of Malnutrition. *Pub. Health Nurs.* 35, 2:87 (Feb.), 1943.

Syphilis in Alabama—Of about 200,000 blood tests taken on draft registrants, 9 per cent were positive. Of the white men 1.5 per cent were positive and of the Negroes, 19.8 per cent. Urban rates were materially higher than rural and the bigger the city the worse the record. As Alabama has a million Negroes, the magnitude of its venereal problem is evident.

GILL, D. G., *et al.* Syphilis in Alabama as Revealed by a Serologic Survey of Selective Service Registrants. *Ven. Dis. Inform.* 24, 1:6 (Jan.), 1943.

Industrial Hazards Peculiar to Women—Useful recommendations for meeting the peculiar health needs of women in industry are presented in this preliminary report. Here you will find practical discussions about work during menstrual difficulties, before and after childbearing, and during the menopause.

HESELDTINE, H. C., *et al.* Women in Industry. *J.A.M.A.* 121, 11:799 (Mar. 13), 1943.

Honesty Is the Best Policy—At present there are no effective methods available for the prevention of colds. Vaccines are of no practical value. Vitamins fail to prevent colds. "Hardening" the body is useless. The

prevention of other respiratory infections is subjected to similarly competent scrutiny and reported upon with equal candor.

KEEFER, C. S. Control of Common Respiratory Infections. *J.A.M.A.* 121, 11:802 (Mar. 13), 1943.

Making the World Safe—A large group of Negro soldiers were given sulfathiazole before and after leaving camp. The gonorrhea rate dropped from 171 to 8 and the chancroid rate from 52 to 6.

LOVELESS, J. A., AND DENTON, W. The Oral Use of Sulfathiazole as a Prophylaxis for Gonorrhea. *J.A.M.A.* 121, 11:827 (Mar. 13), 1943.

North Carolina Does It—More work—fewer workers. The North Carolina Health Department was faced with this problem—as what state hasn't been—and proceeded to do something intelligent about it. Whoever you are, and whatever may be your job, you will be immensely impressed with what was accomplished.

MOUNTIN, J. W. A Self-help Solution of State Personnel Problems. *Pub. Health Rep.* 58, 8:297 (Feb. 19), 1943.

It Worked with Cows—All will admit that cows are more important than women and men! But in Minnesota, a project is under way to apply methods similar to those that have cleared the county of bovine tuberculosis—the greatest hygienic feat in recorded history—to ridding the state, county by county, of human tuberculosis. Belief is expressed that accreditation of counties has done more to stimulate action in preventing the spread of human tuberculosis, than any other movement. You'll be interested in this.

MYERS, J. A. County Accreditation Plan for Tuberculosis Control. *J.A.M.A.* 121, 12:921 (Mar. 20), 1943.

You Can't Argue with a White Rat—How men and women workers were weaned from pastry and soda-pop luncheons to salad sandwiches and milk is told briefly by one who did it.

PAGE, E. S. Nutrition Education at the Fisheries. *J. Home Econ.* 35, 3:156 (Mar.), 1943.

All White Bread Is Ordered Enriched—In the average American's diet, restoration of thiamin in white flour to whole wheat level helped greatly, but does not entirely correct the well known deficiency in that food factor, and enrichment with riboflavin to whole wheat level will not correct the usual dietary deficiency in this second factor. In this report are many interesting comments on carbohydrate consumption.

WILLIAMS, R. D., *et al.* Evaluation of Nutritive Contribution of Enriched White Flour. *J.A.M.A.* 121, 12:943 (Mar. 20), 1943.

"Education" Means To Lead Out—You can fairly easily get people to pay taxes for protection against epidemics, but it is another matter to get them to provide for housing, medical care, and social security—to promote national health. Health education is going to have much harder sledding in the future, the easy jobs of motivation have been done, says this wise man.

WINSLOW, C.-E. A. Health Education in a Democracy. *Science* 97, 2513:189 (Feb. 26), 1943.

It's about Time—Boiling garbage for ½ hour will kill trichinae, and will prevent the infection of garbage few hogs, the chief source of trichinosis. Why not demand this safeguard everywhere?

WRIGHT, W. W., AND BOZICEVICH, J. Experiments in the Cooking of Garbage for the Destruction of Trichinae in Pork Scraps. *Pub. Health Rep.* 58, 10:396 (Mar. 5), 1943.

ASSOCIATION NEWS

THREE-DAY WARTIME PUBLIC HEALTH CONFERENCE AND
SEVENTY-SECOND ANNUAL BUSINESS MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
New York, N. Y., October 12, 13, 14, 1943

COMMITTEE ON STANDARD METHODS OF FOOD UTENSIL SANITATION

A new committee on Standard Methods of Food Utensil Sanitation has been appointed by the Committee on Research and Standards. Walter D. Tiedeman, M.C.E., Chief of the Bureau of Milk Sanitation, New York State Department of Health, will act as *Chairman*.

This new committee will have representation from the Laboratory, the Engineering, the Health Officers, and the Food and Nutrition Sections. It replaces three earlier committees, all concerned with the same problem, namely, the Subcommittee on Standard Methods for the Examination of Dishwashing Devices of the Committee on Research and Standards, the Committee on Disinfection of Dishes and Utensils of the Engineering Section, and the Committee on Food Utensil Sanitation of the Food and Nutrition Section.

Because of the widespread interest in the problem of food sanitation, the Committee on Research and Standards hopes that this representative group will be able to formulate a statement of what constitutes good practice in this field from the technical point of view. When the other members of the committee are appointed their names will be announced in the *Journal*. In the meantime, Mr. Tiedeman will welcome

suggestions from the membership as to how the committee can best serve the purpose for which it was created.

NEW SECTION ON SCHOOL HEALTH

It will be recalled that the Governing Council at the 71st Annual Meeting in St. Louis authorized the creation of a new Section on School Health and, in accordance with this resolution, the Executive Board has designated the following persons to constitute a Section Council to hold office until the close of the next Annual Meeting, at which time the regular routines can be established.

The following Council was recently authorized:

Chairman: Leona Baumgartner, M.D., New York, N. Y.

Vice-Chairman: Jessie M. Bierman, M.D., M.P.H., San Francisco, Calif.

Secretary: George M. Wheatley, M.D., New York, N. Y.

Section Council: Ruth E. Grout, Ph.D., Washington, D. C.; Hortense Hilbert, R.N., New York, N. Y.; Harold H. Mitchell, M.D., Astoria, Long Island, N. Y.; N. P. Neilson, Ph.D., Washington, D.C.; George T. Palmer, Dr.P.H., New York, N. Y.

Dr. George M. Wheatley, Secretary, in conference with the members of the Council, is planning a program for the meeting to be held in New York, N. Y., on October 12 to 14, 1943.

Members who wish to affiliate with the new Section should so advise the Central Office.

A.P.H.A. MEMBERSHIP RECORD

Elsie A. Siemer, of the A.P.H.A. staff and in charge of the Membership Department, has announced that the month of March, 1943, has broken all membership records for the A.P.H.A., with 207 new members listed.

According to Miss Siemer, this has grown out of the excellent coöperation afforded by members and Fellows of

the Association in returning the lists of suggested new members.

SPARE COPIES OF THE JOURNAL NEEDED

Readers are asked to address spare copies of the July, 1941, August, 1941, and January, 1942, issues of the *American Journal of Public Health* to the offices of the Association, where they will be most welcome.

APPLICANTS FOR MEMBERSHIP

NATIONAL HEALTH HONOR ROLL

Names of 33 cities and counties in 18 states winning awards in the 1942 National Health Honor Roll have been announced by the United States Chamber of Commerce and the American Public Health Association, which jointly sponsor this annual competition in community health promotion and preservation.

Those cities which attained the 1942 National Health Honor Roll are:

Baltimore, Md.
 Detroit, Mich.
 Evanston, Ill.
 Greenwich, Conn.
 Hackensack, N. J.
 Hartford, Conn.
 LaSalle-Peru-Oglesby, Ill.
 Madison, Wis.
 Milwaukee, Wis..
 Newton, Mass.
 Peoria, Ill.
 Racine, Wis.
 Reading, Pa.

Gibson County, Tenn.
 Glynn County, Ga.
 Jones County, Miss.
 Lauderdale County, Miss.
 Louisville-Jefferson County, Ky.
 Madison County, Ky.
 Memphis-Shelby County, Tenn.
 Olympia-Thurston County, Wash.
 Saginaw County, Mich.
 Sanilac County, Mich.
 Santa Barbara County, Calif.
 Van Buren County, Mich.
 Washington County, Miss.
 Whitman County, Wash.

Those counties which attained the 1942 National Health Honor Roll are:

Arlington County, Va.
 Davidson County, Tenn.
 El Paso County Tex.
 Fayette County, Ky.
 Forsythe County, N. C.
 Gallatin County, Mont.

Awards were presented to the winners during the Chamber's annual meeting, held in New York, April 27 to 29.

The National Health Honor Roll is financed jointly by the W. K. Kellogg Foundation and the Metropolitan Life Insurance Company.

(b) Physician to take charge health association operating small hospital; \$400, partial maintenance; Arizona. (c) Director of district health department; training or experience in public health, preferably in administrative side, desirable; \$4,500, plus traveling allowance. (d) Clinician; venereal disease clinic; patients average 1,000 weekly; Southeast. (e) Public health physician; mostly venereal disease work; vicinity Washington. (f) City health officer; town of 10,000 located in the Shenandoah Valley; will have as assistants full-time nurse and sanitary officer. (g) Industrial physician; construction project; Alaska; \$4,000, maintenance; transportation. (h) Field position; state department of health; should be effective public speaker; will provide health training if not trained; Midwest. (i) Public health appointment; \$250, including traveling expenses; South. PH3-1. Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

PUBLIC HEALTH NURSES—(a) Public health nurse; minimum year's experience in recognized health department; Northern California. (b) Public health instructor; fairly large hospital; East. (c) Public health nurse; two-county health department; generalized program; staff consists of director, sanitarian, four staff nurses, three clerks; must be able to drive; \$1,800 plus car allowance. (d) College nurse; approximately 1,500 students; public health certificate required; \$2,000; West. (e) Public health supervisor; graduate nurse with public health certificate and considerable executive experience required; \$2,200; West. (f) Resident nurse; young women's college; Midsouth. (g) Staff nurse; state department of health; South; if not trained will provide training during which time salary will be received. PH3-2. Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago.

EMPLOYMENT SERVICE

The Association Employment Service seeks to bring to the attention of appointing officers the names of qualified public health personnel and to act as a clearinghouse on employment. This is a service of the Association conducted without expense to the employer or employee.

From the registry of persons available, selected announcements are published from time to time. Appointing officers may obtain lists of all registrants on request.

Address all correspondence to the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y.

POSITIONS AVAILABLE

Southern state department of health seeks several obstetric and pediatric consultants, requiring a minimum of a year's residency in a specialty, immunity to draft and preferably training in public health. Men and women are eligible. Salary \$300 per month plus travel. Apply Box C, Employment Service, A.P.H.A.

MEDICAL OFFICERS NEEDED—TENNESSEE VALLEY AUTHORITY

The Tennessee Valley Authority is in urgent need of medical officers who are not eligible for military service and who are willing to accept assignments to war industrial activities (construction, manufacture of war chemicals and manufacture of hydroelectric power) as their participation in the all out war effort. Responsibilities include physical examinations, industrial hygiene, care of injuries, medical care to families in remote construction areas and general public health responsibilities in construction camps and villages.

Salary ranges from \$3,200 to \$4,200 per annum with opportunity for promotion.

For further information write to Dr. E. L. Bishop, Director of Health, Tennessee Valley Authority, Chattanooga, Tenn., or to the Personnel Department, Tennessee Valley Authority, Knoxville, Tenn.

CAREER OPPORTUNITIES IN PENNSYLVANIA

Charles B. Frasher, Merit System Supervisor, Pennsylvania State Department of Health, 207 Blackstone Building, Harrisburg, announces that appointments will soon be made in the following branches of the State Health Department of Pennsylvania: Health Conservation, Tuberculosis Control, Venereal Disease Control, Pneumonia Control, Industrial Hygiene, Narcotic Drug Control, Environmental Hygiene, Public Health Laboratories, Maternal and Child Health Services, Crippled Children's Services, School Medical Inspection, Dental, Nutrition, Milk Sanitation, Public Health Education, Sanitary Engineering, Vital Statistics, Public Health Nursing, Accounts, Biologicals and Supplies, Merit System, Tuberculosis Sanatoria. Open competitive examinations will be held and the resulting lists are

expected to be in existence for 2 years or longer. Residence requirements are waived for professional positions.

INDUSTRIAL HYGIENISTS

The Research Section of the Division of Industrial Hygiene, National Institute of Health, Bethesda, Md., needs chemists, physicists, and medical technicians, as well as laboratory assistants in these fields. There is also opportunity for persons without college education, specific training or experience who are interested in such positions. Women now form one-third of the employees in the Research Section.

Wanted: School Dental Supervisor to administer and operate dental program in City schools and clinics in City 50,000 population. Salary \$3,000 to \$3,600 with travel allowance. Those interested should address Dr. W. A. Browne, City Health Department, Alexandria, Va.

The Milwaukee City Service Commission announces an examination for assistant chief in charge of sanitary inspection. Salary first year \$210 per month increasing by \$10 increments annually until a maximum of \$260 per month is reached. Applicants must be citizens of the United States, between 25 and 45 years of age. Those interested may communicate with the Milwaukee City Service Commission, Room 716, City Hall, Milwaukee, Wis.

Sanitarian wanted in county of 28,000 in Midwest. Salary \$1,800 plus \$500 travel. Must own car. Complete supervision and execution of sanitation program, including milk, water, food-handling, etc., and general sanitation of environment in county. Address Box I, Employment Service, A.P.H.A.

Merit System for Personnel Administration, Delaware, is accepting applications for position of Deputy State Health Officer in Delaware State Board of Health. Salary range \$3,600 to \$4,200. Applications accepted until further notice. Those interested should communicate with Merit System Supervisor, P. O. Box 1911, Wil-

mington Delaware, or State Board of Health, Dover, Del.

Sanitarian wanted: Starting salary \$1,800 per year with travel allowance of \$50 per month. Man must have own car. Bachelor's degree followed by at least one year's course or its equivalent in subjects necessary for one entering the public health field, or an engineering degree plus one year's experience in sanitary or public health engineering required. A course in public health training may be considered as an equivalent for a part of the experience requirement. Apply Dist. Dept. of Health No. 6, Central Office, Newberry, Mich., Dr. Franklin.

Notice of an expected vacancy for an Industrial Hygiene Engineer in the Los Angeles County Health Department has been received. Those interested should communicate with Dr. H. O. Swartout, Acting County Health Officer, Los Angeles, Calif.

Announcement is made of the following examinations to be held by the State Personnel Board, Seattle, Wash., for positions in the State Department of Health and County Health Departments:

Position	Salary Range	
	Entrance	Maximum
Bacteriologist	\$135	\$160
Laboratory Assistant ..	125	145
District Public Health Officer, II	325	425
Public Health Nurse ..	145	170
Asst. Venereal Disease Investigator	150	190
General Sanitarian	160	200
Milk Sanitarian	160	200
Chief of Public Health Education	275	335
Senior Milk Sanitarian	190	230
Obstetric Consultant ..	375	450
Pediatric Consultant ..	375	450
Senior Bacteriologist ..	160	200
Assistant Sanitarian (Open to Men and Women)	125	150

Residence in the State of Washington is not required. Applicants must be citizens of the United States. Persons interested may secure application forms from the State Personnel Board, 1209 Smith Tower, Seattle, Wash.

FOR OTHER POSITIONS AVAILABLE WRITE EMPLOYMENT SERVICE, AMERICAN PUBLIC HEALTH ASSOCIATION, 1790 BROADWAY, NEW YORK, N. Y.

In view of the current active demand for trained and experienced persons in public health it is suggested that prospective employers communicate directly with the Employment Service, American Public Health Association, 1790 Broadway, New York, N. Y., for up-to-date lists of applicants.

POSITIONS WANTED

Physician, age 36, M.D. Iowa, Dr.P.H. Harvard, specializing in tuberculosis, seeks position as medical director of a sanatorium or a state bureau of tuberculosis. Exempt from military service. A-476

Physician, M.D. Yale, with private practice industrial medicine. Age 39 and draft exempt. Seeks opportunity as public health physician. A-505

Physician, M.D. University of Arkansas, M.P.H. Harvard, experienced as county health officer. Age 35. Will consider position as city or county health officer or director of a bureau. A-506

Bacteriologist, 28, Iowa State College, draft immune, 3 years' experience public health laboratory. Experience in investigation and control activities on water, sewage and sanitation, as chemist and bacteriologist and serologist in syphilis and enteric diseases. L-465

M.D., Dr.P.H., now a practising physician, chief of a clinic, diplomate in his specialty, professor in a medical school, ineligible for military service but in good health, wishes to make a change in his work and be employed in war industry. A-504

NEWS FROM THE FIELD

EXTENSION OF PUBLIC HEALTH COVERAGE TO THE NATION

Editorial, J.A.M.A., April 3, 1943

"Forty million of our people live in communities or in areas in which there is no access to the full-time services of a professionally trained medical officer of health and the associated sanitarians and public health nurses of a local health department of civil government. On June 10, 1942, the House of Delegates of the American Medical Association unanimously voted its approval of extension of such services. Now the Committee on Administrative Practice, one of the standing committees of the American Public Health Association, has offered a plan to improve the situation.

"Tax supported public health services have been distributed unevenly and not in all respects in relation to sanitary needs or in proportion to the population units of local government. In fact, there are conditions of local government, cities, townships and counties, in which duplicating and to some extent conflicting health services are provided because of local rivalries of a political nature. State laws in some instances do not authorize co-operative arrangements for a single health officer for adjacent communities or counties. Good health service for prevention of communicable, occupational, nutritional and other preventable diseases, and for the protection of the health of mothers and children, cannot be achieved for a state solely or effectively or economically by a state department of health unless the counties and cities are sufficiently concerned with local health conditions to support their own community health services. By the same token federal programs for a higher level of national health fail in

effectiveness for lack of facilities of local government through which federal grants can be used by agreement with the state.

"In July, 1942 some 62 million people living in the continental United States were provided by local governments with full-time medically officered health protection. In addition 16½ million persons were served by county or district health departments operated by a state department of health, and about 12 million more people living in cities with full-time health services. There remain 41,052,600 persons, or 31 per cent of our population, in 1,687 counties in 41 states for whom no full-time health service is provided by either local or state government.

"The committee of the American Public Health Association presents a half dozen basic principles of health administration and suggests that not more than 1,127 units of local health jurisdiction are needed for the total coverage of the continental United States. The units are, of course, in addition to the respective state departments of health and the health services of the various bureaus and departments of the federal government. It is to be assumed that a city and the county within which it is located shall have a single headed health service. It is suggested that a unit of less than 50,000 population can rarely maintain an efficient tax supported local health service and that counties with small populations should be authorized by state law to combine with adjacent counties to support and be served by a single district or multi-county health department.

"Among the 3,070 counties of our

states there are many with populations so small and economic resources so slender as to preclude the possibility of supporting even the minimum personnel and functions of a local health department. The basic public health law of each state should not only permit but specifically authorize the creation of local health units of population size and area compatible with efficient and economical public service. The law should provide furthermore for the selection of professional personnel on a sound civil service or merit system and authorize the levying of taxes to support the health services.

"The American Public Health Association, through its Subcommittee on State Health Administration, has recently completed a study of state health administration in Illinois, undertaken at the request of the state director of public health with the approval of the governor. A summarized report of this study discloses a recommendation that legislation be enacted to permit the establishment of full-time county or combination of county health departments. Following a distribution of this report, the Research Department of the Illinois Legislative Council made available a factual study of county health departments in the state for use by the general assembly in considering any legislation that might be proposed. Now a bill has been introduced by Senator Searcy as S. 244, authorizing the establishment and maintenance of county and multiple county health departments in the state.

"Permissive in form, this legislation proposes that county full-time health departments may be created either by resolution of a county board or by the voters of a county and that multiple county health departments may be set up. If four or more counties wish to associate themselves in establishing and maintaining such a department, prior approval must be obtained from the

state department of public health. Provision is made for the levying of a special tax not to exceed 1 mill on the dollar on all taxable property in the county or counties involved to finance the operation of the department. Existing full-time health departments in cities, villages or public health districts with less than 500,000 inhabitants may be retained or they may be abandoned and become integrated in the county or multiple county health department. Health departments in communities with a population of 500,000 or over will apparently not be affected by the bill. Each county health department will be managed by a board of health appointed by the president or chairman of the county board. At least two members must be physicians licensed in Illinois to practice the healing art in all its branches and at least one member must be a dentist licensed in Illinois. All members must be chosen for their special fitness for membership on the board. Multiple health departments are to be managed by a board of health consisting of three members appointed from each county by the president or chairman of the county board.

"Provision is made for the appointment of medical, dental and nonmedical advisory committees and for the appointment, for each department, of a chief medical officer to act as executive officer, and of such other officers and employees as may be approved by the executive officer, all appointees to meet the qualifications prescribed by the Illinois State Civil Service Commission. The functions to be exercised by the departments are set forth in broad groupings, including the right to pass such rules as may be necessary for the improvement and protection of the public health. The people of Illinois may well reflect on the importance of this proposal, establishing as it does a framework on which may be con-

structed a comprehensive public health program to function in the interest of the health of all the people of the state. Legislation with a similar objective, although differing in detail and approach, was proposed this year in the states of Arkansas, Georgia, North Dakota, Utah, Washington and Wyoming.

"Each state medical society may with advantage avail itself of the detailed information in the hands of the American Public Health Association and analyze its own situation in conference with its own state health officer. Permissive or enabling legislation to provide for local health units and their support should be supported by the professional influence of the physicians of the state, unless existing laws are adequate.

"The career of public health as a specialty of medicine requiring graduate university training and practical experience is so far accepted as part of the pattern of preventive medicine that the survival of the part-time general practitioner as the local administrator of a health department cannot be encouraged by the medical profession or be recommended to the taxpayer as the best his money can buy in public health."

FORTY-FIRST ANNUAL MEETING STATE AND TERRITORIAL HEALTH OFFICERS

The 41st Conference of State and Territorial Health Officers with the U. S. Public Health Service was held March 24 in Washington and was opened by Surgeon General Thomas Parran.

The Annual Conference is an outgrowth of the coöperative program established many years ago by the federal agency with the states for the control of epidemic diseases. On this foundation of state responsibility and federal assistance, the national public health program of the United States has been

established. At the yearly conference, the Public Health Service presents the states with a summary of current problems of nation-wide significance. The State and Territorial Health Officers in turn discuss mutual problems and present recommendations for their solution to the Surgeon General.

In opening the Conference, Dr. Parran reported that, despite difficulties in obtaining critical materials for the construction of community health facilities recommended by the Public Health Service, 153 hospital and health center projects and 372 sanitation projects were either completed or nearing completion on February 15, 1943.

The Surgeon General warned the health officers that if the government finds it necessary to move a large number of farm workers into certain areas this year for the production of food crops, the need for rural health and medical services will be intensified. "Until the scope and organization of such a plan are clearly defined, it is impossible to say just what it will entail," he said, "but we must obviously be prepared to assume responsibility in whatever program is evolved."

Assistant Surgeon General Joseph W. Mountin, in charge of the States Relations Division, told the Conference that the Public Health Service has recommended to the Budget Bureau the appropriation of federal funds totalling \$34,399,521 for federal-state coöperative health work in the fiscal year 1943-1944. This sum includes regular appropriations for health activities under Title VI of the Social Security Act and under the National Venereal Disease Control Act, as well as emergency appropriations for health services directly connected with the war effort. The latter include malaria and yellow fever control around military establishments where these diseases are prevalent, industrial hygiene services, tuberculosis control in war industries, and

protection of municipal water supplies from sabotage.

Dr. Mountin also called upon the health officers for greater financial participation by state and local governments in protection of the public health during the emergency. State and local health departments may expect to lose more personnel as the needs of the armed forces increase. The state health departments of North Carolina and Tennessee were cited by Dr. Mountin as the only ones which have anticipated this contingency by organizing state-wide programs to recruit and train new personnel as substitutes for permanent employees who have gone into military service or other employment.

NATIONAL HEALTH SERVICE IN BRITAIN
—A REPORT OF THE BRITISH SOCIETY
OF MEDICAL OFFICERS OF HEALTH

Public Health, the Journal of the Society of Medical Officers of Health, London, in the January, 1943, issue carried a report on the national health service as it should be, as prepared by the Society. The foreword points out that health is a national asset and every member of the community should be entitled to the best possible health and its minimum disturbance by disease or any adverse condition. The Society was established in 1856 for the advancement of public health. In September, 1941, the Society set up a Medical Planning Committee to consider how the health of the nation could be best secured. An interim report was prepared which has finally resulted in this report on a national health service as a contribution by professional men and women with wide experience in planning for health.

An introductory section describes the present governmental functions in Great Britain as they relate to health.

Having regard to these provisions and the need for their coördination and expansion, what is required is that in any local government area there should be a single authority

for health purposes. Such an authority would be responsible within its area for the administration of medical, health and allied services, including the environmental and personal health services, and be further responsible for the provision of an adequate hospital service for all the inhabitants of its area.

In the new organization of medicine it cannot be too strongly emphasized that it will be general practitioners or groups of practitioners who will be in the first lines of defense against the encroachment of disease and for the maintenance and improvement of health. The family should be regarded as the health unit, and practitioners should have the care in health as well as disease of suitable numbers of persons.

The report pictures a health center equipped for services of preventive and curative medicine, and points to the doctor as the essential element in the organization with facilities for giving effect for the purposes of national medicine, namely, to maintain and improve health, to prevent disease, and to treat disease and reestablish health. "The doctor in this organization becomes the real family doctor with full responsibility for the health of the persons under his care."

Hospital services are proposed as complete services able to deal with all forms and stages of invalidity. "Any suggestion to create *ad hoc* hospital authorities for the purpose of administering hospital services would create fresh confusion in a field where integration is essential." Both voluntary and municipal hospitals would be included and areas would be so arranged that at least one hospital will come to be regarded as a principal hospital. Provisions for teaching services are included.

All hospitals, voluntary and local authority, should be available for all members of the community on similar terms and conditions.

An adequate laboratory service forms an essential part of an efficient medical service and should be conducted so as to insure regular personal contacts between the staff of the laboratory, the officers engaged in epidemiology and other public health work, the clinical staffs of hospitals and the medical practitioners in the area.

It is proposed that staffs for the most part should be on a whole-time salary basis, though provision is also made for a capitation basis as under the National Health Insurance system and as well as part-time service on a salary basis.

It will take time for a new type of medical practitioner to be trained for the care of persons in health as well as disease. Hitherto the education and training of the medical practitioner have mainly had regard to the cure of disease. Future training must also embrace the study of the prevention of disease and the maintenance of health.

Having regard to the foregoing considerations it would appear that to avoid any unnecessary delay in the ultimate operation of the plan steps should be taken at the earliest possible moment: (1) To establish a new Health Ministry with health as its sole function; (2) to establish new Local Government Areas; and to give powers to the new Local Government Authorities to plan and develop their hospital, medical, health and allied services within their discretion and according to circumstances during the transition period.

Having regard to the probable state of medical practice immediately after the war, it is suggested that steps might be taken to ameliorate the post-war situation by empowering major local authorities to set up a whole-time salaried domiciliary service on lines which would ultimately fit into the scheme outlined in this report.

FOR BETTER MEDICAL CARE

Editorial, New York Times, April 2, 1943

"The American Public Health Association's Committee on Administrative Practice has issued a report* which deserves earnest consideration because it suggests a plan for the better distribution of medical care. As matters stand, 62 million of our continental population receive some medical attention from local governments, 16.5 million more from county or district health departments, and 12 million from municipal hospitals and health officers.

This leaves about 41 million for whom no full-time health service is provided. It is with this large fraction that the Association's report deals.

"The Association makes the point that in addition to existing agencies, 1,127 medical units are needed for the continental United States. This relatively small addition is held to be adequate if counties so sparsely settled that they cannot support a good health organization are willing to consolidate their funds and facilities and establish a single large unit for the benefit of the group. That this is no utopian proposal is made clear by a study of Illinois' needs.

"Legislation is proposed to permit counties to create group health departments, the permission to be obtained from the State Health Department. How is the money to be raised? By a tax of one mill on the property of counties involved. Communities of less than 500,000 inhabitants may either retain or abandon their health organizations as expediency dictates. Larger communities would not be affected at all.

"This plan clearly has its merits. The cost is not large, and there is nothing compulsory about it. In these days of the automobile and the bus, an adequate health organization should have no difficulty in covering hundreds of square miles. But does the plan go far enough? The sick too often need hospital care. And if there are to be hospitals they should be open to all qualified physicians. Moreover, some provision should be made for research in public health of the type in which this city has promised to engage, and for teaching. No sound medical plan can ignore the interrelation of practice, research and teaching."

DR. DOULL SERVING OVERSEAS

James A. Doull, M.D., Dr.P.H., Professor of Hygiene and Public Health, School of Medicine, Western Reserve

* Unit of Local Health Service—Progress Report, Committee on Local Health Units. Haven Emerson, M.D., Chairman. *A.J.P.H.*, 33, 4:404 (Apr.), 1943.

University, Cleveland, has recently undertaken an overseas mission for the Lend-Lease Administration. Dr. Doull is a member of the Executive Board of the American Public Health Association. He has been appointed Senior Surgeon (R) in the U. S. Public Health Service and assigned to the Lend-Lease Administration.

During the last World War Dr. Doull served in the Medical Corps of the British Army for four years and was awarded the Military Cross of Great Britain and the Croix de Guerre of France. He expects to return in about four months.

APPOINTMENT OF JUDICIAL COMMISSION ON BACTERIOLOGICAL NOMENCLATURE

At the Third International Congress of Microbiology held in New York City in September, 1939, a series of recommendations of the Permanent International Committees on Bacteriological Nomenclature were accepted at the plenary session of the Congress. The third and fourth recommendations were:

That the Nomenclature Committee, as at present constituted, shall continue to function under the auspices of the International Association of Microbiologists as it did under the International Society for Microbiology.

That the International Committee shall select from its membership a Judicial Commission consisting of twelve members, exclusive of members *ex officio*, and shall designate a Chairman from the membership of the Commission. The two Permanent Secretaries of the International Committee on Bacteriological Nomenclature shall be members *ex officio* of the Judicial Commission. The Commissioners shall serve in three classes of four commissioners each for nine years, so that one class of four Commissioners shall retire at every International Congress. In case of the resignation or death of any Commissioner, his place shall be filled for the unexpired term by the International Committee at its next meeting.

By prompt action at and subsequent to the Congress ballots were cast in spite of war conditions by 26 of the 62 members of the Permanent Committee

on Nomenclature. These ballots when examined by the undersigned joint Secretaries of the Permanent Committee in November, 1942, were found to have resulted in the selection of the persons whose names appear below. These are grouped in the three classes specified by the Permanent Committee, those receiving the highest number of votes being placed in the nine year class, those receiving the next highest in the six year class, etc. Names in the classes are arranged alphabetically.
